Hand Labour.—Men are not much required at present, except in those cases where a fall of timber has occurred, in which case the sooner the timber is hewn and squared the better; the bark and faggots if not yet removed, especially on land under crops, may be with advantage cleared away as soon as possible. Burning compost heaps should be attended to immediately in order that the materials may be in a mellow and fit state to lay out after the hay from the pastures has been removed. On pastures also which may have been close fed by dairy cows or young stock during the summer, any such compost may be applied with benefit either just before or directly after harvest, for after being properly spread and chain-harrowed it will improve the growth of grass during the autumn immensely, and in early winter also with open weather and during seasonable rains. Weeding Wheat and other crops, especially

Clovers, should now be done. This has always been women's labour formerly, but in some districts it must now be done by old or infirm men or boys, greatly to the disadvantage of the former. In the chalk and other soils where Charlock abounds and proves almost an impossibility to eradicate it we recommend, where no couch grass is in connection with the Charlock, that it should be ploughed down and the land harrowed immediately, in order that another successive lot of seed may vegetate, and that also this growth may be ploughed in just as it is coming into bloom. This may be done with great advantage, or as much advantage as Mustard is now treated, and if three or four crops can be ploughed-in at varying depths the land will be manured, and if this plan be carried out, followed between two cereal crops, such as Wheat and Lent corn, the land would be permanently improved, for in the death and decay of the Charlock a vegetable humus will be formed, and permanently benefiting the land. At the same time by repeated deep and deeper ploughing the land may be ultimately freed from this seriously damaging weed if persisted in for several years in succession, and also during the growth of corn, using the implement drawn by one horse, called Koldmoo's weed-eradicator, which pulls off the heads of Charlock as it is drawn across the corn without injuring the cereal plants if done at the right time. In this way we accomplish several objects simultaneously—that of freeing the land from a noxious weed, and manuring the land as well as following it, under the operations and preparations of one or several years as may be necessary. We know nothing so effectual and economical as this plan if properly carried out.

Live Stock.—In all those districts where the horned Dorset and Somerset ewes are kept in the south-western counties it is now time on the breeding farms to select all the off-going ewes for sale in the autumn, to purchase some good South Down rams to run with the ewes, and if the ewes are retained in their wool, and not shorn until all the ewes prove in lamb, they will generally bring their lambs in the two best months for early lambs to fall—viz., October and November. On the sale of the ewes to be fed on the vale farms of the south and home districts they will be sure to command the highest price in the autumn at Weyhill and other fairs where these ewes are sold. On the breeding farms, however, and especially on the dry healthy limestone and chalk soils of the south-west counties, the ewes for breeding are generally mated with the horned rams, but not until the month of November. At the same time it should be remembered that, however requisite it is to have good ewes, yet the careful selection of rams bred from the choicest ewes of the choicest flocks in the district is a matter of the highest importance; in fact, it is seldom that sufficient care is used in this respect, even by those breeders who may have a stock of rare quality ewes, but to maintain these the rams always have an important influence in the succession, and much more than they are often credited with.

OUR LETTER BOX.

Preparing for Hay Ricks (S.T.W.).—In preparing a stand or steddle to build ricks of hay upon, it is a good plan to use some stout faggots, so that there may always be a free circulation of air passing through them at all times after the ricks are made. It is also a good method of protecting the bottom of the rick to make a trench about 12 inches wide and 9 inches deep all round to take away freely all water which drips from the eaves of the rick. Some method of protecting the hay which is being stacked is requisite, otherwise in the event of a sudden thunderstorm serious damage may occur. We consider the outlay for the purchase of a large sailcloth and poles is money well spent, and if the poles are erected so that at short notice the covering cloth may be available, no hay need be damaged whilst the rick is building. The size and shape of the ricks is a matter of some importance; for although large ricks to contain 30 or 40 tons may be best for the day, there being less outside and waste, yet, when the season is uncertain, 20 tons are enough for one rick, as it is more quickly secured.

REMARKS.

- 4th.—Hail shower at 10.15 A.M.; generally fine after.
 5th.—Fine early, shower at 11.30, thunderstorm at 1.45 P.M., and showers later.
 6th.—Fine until 5.15 P.M., then showery till 8 P.M.
 7th.—Dull, with slight showers, fine at night.
 8th.—Fine throughout, but cloudy in evening.
 9th.—Fine and warm; lunar halo at 10.30 P.M.
 10th.—Splendid day, the first on which the temperature reached 70°.

The early part of the week cool, but the last two days warm, so that the average for the whole week is just the mean for the season.—G. J. SYMONS.

DOUBLE ZONAL PELARGONIUMS.

AS far as actual beauty is concerned I freely admit that the single varieties of Zonal Pelargoniums are decidedly preferable to these, but for general utility they by no means equal the double, or rather the semi-double, flowering sorts. For affording a continuous supply of trusses during the late autumn, winter, and spring months the latter are invaluable. A few plants of each variety I shall recommend for winter flowering may perhaps be found in innumerable gardens, but this is a proof that they are not appreciated or dozens would be grown. We have by no means a great amount of house room, yet we contrive to give up one house to semi-double Pelargoniums from the end of September to the beginning of June, a late crop of Melons being grown in the meantime. All cannot devote a house to similar purposes, but there are many gardens where a much larger house might with advantage be occupied with Pelargoniums during the winter and spring months, while in smaller gardens part of a forcing house may profitably be given up to them.

CULTURE.—Their cultural requirements are very simple, and I shall only briefly detail them, the object of this paper being to induce others to commence their culture on a much larger scale. We find that the old plants cut back, repotted, and grown for winter do not prove so satisfactory as young plants, as they form too long-jointed sappy shoots, and these are not of a floriferous description. We raise a given number of plants each year, and also reserve a certain number of the best young plants of the previous season's rearing, and these are not cut back. In this manner we have plants of various heights, and which are necessary for effective arrangement. The cuttings are struck in heat during April, are stopped when rooted and commencing to grow, potted off if struck several cuttings in a pot, or given a shift if they are struck singly in small pots. They are kept growing in heat, always, however, in a light airy position, pinched back once or twice to make them bushy, and given another shift, this time usually into their flowering pots. Any good sandy loamy soil suits them.

Early in June the pits and frames are cleared of the summer bedding plants, and some of them are then filled with the Pelargoniums. Here they receive careful attention in watering and ventilation, and are kept from flowering. During dry weather the lights are drawn off, but I do not believe in the "baking" often considered necessary either for these or for the single-flowering varieties intended for the late autumn and winter display. Our aim is to keep them quite green and growing slowly, and if we do not secure quite so much bloom at first the trusses are much finer and more continuously developed. If it is advisable to protect or lightly shade them from very bright sunshine it is of still greater importance that the plants be sheltered from heavy winds and saturating rains.

Most of our young plants are flowered in well-drained 8-inch pots, and those reserved for next season's display,

No. 204.—VOL. VIII., THIRD SERIES.

when removed from the forcing house in June, are hardened and then given a shift into 10-inch pots. One good stake is placed in the centre of each, and to this the principal branches are loosely tied. They are thus neither bushes nor pyramids, but more correctly pillars. These, too, are sheltered in deep pits as much as possible, and encouraged to form short-jointed yet healthy growth. At the outset, not having any large old plants, we struck six cuttings in a pot and grew these without stopping, this resulting in large serviceable specimens, as all the sorts are given to branching.

All should be housed by the middle of September and commence blooming at once. They will not be continuous-blooming in a greenhouse temperature, but succeed to perfection in a light forcing house, especially if stood on a staging over the hot-water pipes. A very high temperature and a moist atmosphere are more conducive to luxuriant growth than to floriferousness; we therefore never syringe or damp the house, and maintain a temperature ranging from 55° to 60° by night and 60° to 65° in the daytime, with a further increase with sunshine and air.

Plenty of room should be given, as I find that a few plants standing clear of each other yield more flowers than a greater number crowded together. Water is given carefully, especially during the dull winter days, when it is advisable to keep the plants slightly dry, or the growth will be too rapid and too soft to bloom properly. For the same reason liquid manure or a light top-dressing of some kind of artificial manure should not be given till it is seen the plants are losing colour for want of some fertiliser, and even then it is preferable to apply it in a weak form.

SELECTION OF VARIETIES.—Much depends upon the choice of varieties. I can only recommend five or six, and though two of these may be improved upon, as far as numbers are concerned they are ample. The most noteworthy variety is Guillon Mangilli, this being, according to my experience, superior to and quite distinct from all other sorts. It forms sturdy branching growth, will yield great numbers of immense trusses of bright crimson flowers all the year round. It is equally as well adapted for small pots as for large ones, is good for summer work, and one of the best for the markets, but the trusses, pips, and colour are best on the plants grown in heat. We frequently cut trusses of it 6 inches in diameter, the semi-double pips being proportionately large. The nearest approaching to it in habit is Mrs. Arthur Lattrey, a charming light pink variety, and which is one of the best for winter forcing. The older Madame Thibaut is of a deeper pink colour, and the trusses are smaller and more globular. This also is good for small pot and greenhouse summer culture, and with a fair amount of sunshine forces well. Madame A. Baltet was at one time relied upon for producing white flowers during the winter, and it has done us good service. It is, however, being supplanted by Candidissima plena, as we find this forces better, and the trusses of bloom, though smaller, are much whiter and less liable to become discoloured by sunshine. E. V. Raspail is the best scarlet we have, but this does not force particularly well, and I shall be glad if some of the readers of the *Journal of Horticulture* will recommend a good substitute. We had both this and Ludwig Ferchl particularly good during the late autumn and early winter months, and both are superior in every respect to the still popular Wonderful. Of flesh-coloured sorts I have grown Asa Gray and Louis Buchner, and am now inclined to give the preference to the former. Neither of them produces large trusses or grows so strongly as any of the above-mentioned sorts, but the colour finds favour and is wanted.

To further demonstrate the value of this class of Pelargoniums I may mention that, for the adornment of churches and other purposes, we cut nearly a bushel of fine trusses in a house 20 feet long and 12 feet wide, and yet left hundreds of others in various stages of development. I find them of great service for packing, dinner-table decoration,

No. 1860.—VOL. LXX., OLD SERIES

hand and buttonhole bouquets, while they are by no means to be despised for mixing in vases with other flowers or for specimen glasses. Indeed they can be utilised in so many ways that they are extremely valuable in gardens, and are deservedly becoming great favourites.—W. IGGULDEN.

A SELECTION OF VEGETABLES.

ONE of the most popular and useful prizes offered for competition at the meetings of local horticultural societies is for what is somewhat erroneously termed a collection of vegetables; but as the number of sorts to be shown is always limited, the title of this paper would certainly be the most correct of the two. But when a society can afford it there should always be two classes—one for an unlimited collection from large gardens of a given area, say from 2 acres and upwards, and another for a limited selection from smaller gardens. This would not only put competitors upon an equal footing, but it would induce many to exhibit in the second class who might otherwise not do so at all, from a mistaken idea that large gardens invariably produce the best vegetables. That large gardens do generally contain an abundant supply of good serviceable vegetables is undoubtedly correct, but the fact of the labour power being spread over so large an area not unfrequently militates strongly against the production of specimen prize-winning vegetables, especially when the rigid economy of hard times has caused a serious reduction in the staff, as is but too frequently the case now-a-days.

The healthy spirit of emulation to which such contests give rise should, and undoubtedly does, lead to a general improvement in the garden produce, and this is the true end and aim of the society. Most local shows are held as summer plenty ripens into the fulness of autumn, and fruit and flowers are most abundant; but after a month or two of hot dry weather vegetables are apt to be neither so fresh, crisp, or succulent as at midsummer. Well will it be now, therefore, to carefully consider ways and means which are generally available for the successful culture of, or rather for the maintenance of an unbroken supply of tender young vegetables during the heat of summer. Water, manure, and labour are our three indispensables, always to be regarded as an inseparable trio ready to our hands in due proportion, and which, if applied with due care and skill, render success a certainty.

PEAS.—These worthily come first as the most popular summer vegetable. It is not often that soil is either deep or rich enough to do full justice to them. Out of five gardens in which I practised only two had really suitable soil for the growth of full crops of late summer Peas. Trenches a foot deep, prepared as if for Celery, must therefore be resorted to in most gardens. If they were 2 feet deep the Pea roots would quickly reach the bottom, but a foot is a reasonable and fairly safe depth. Sow in the first and third weeks of June for a late August and September supply either Telephone or a similar tall-growing sort with large pods well filled with deep-green peas. If the weather is hot and dry, then water the seed well as it is sown, and cover with the warm moistened soil immediately. Germination will follow quickly and simultaneously in the whole of the seed, and not in part of it only, as is frequently the case when it is left to chance in unwatered soil. After growth is visible there must be no check from drought. A thorough drenching of the whole of the soil about the roots once a week, followed by a slight mulching to check evaporation, will suffice; and if sewage can be substituted for the water after the pods appear the crop will be both abundant and fine.

TOMATOES.—Whether grown in pots or not, a sunny airy position under glass is indispensable to the ripening of this important crop. It is a gross feeder, and should have liberal daily supplies of sewage or other liquid manure as the fruit is swelling. Supporting them by stakes, nipping off the tips of the growth one joint above each flower truss, thinning foliage and crowded lateral growth, are the chief cultural points. Fruits of medium size, handsome in form, and without ribs are best for table, and ought therefore to obtain preference before very large fruit at an exhibition. There are many excellent varieties, of which Acme and Vick's Criterion may be mentioned as standard sorts, with fruit of perfect form and high quality.

CAULIFLOWERS.—Really good heads of Cauliflower at the end of a hot dry summer so surely indicate skilful culture that they alone would materially affect the judges' decision. Plants just through the soil, or seed sown early in May, should have good heads by the end of August; but this is a little uncertain and is immaterial, for as a full supply has to be ready before the late Broccoli is over in May, and has to be kept up till the early

winter Broccoli is ready in autumn, due care has only to be taken never to let our supply of compact heads run short, and not only shall we always be ready for an exhibition, but for the household requirements. Trenches containing plenty of manure, frequent thorough soakings of sewage, top-dressings of rough half-decayed manure to check evaporation, and to encourage free root growth near the surface as well as deep down in the trenches, will insure that full development of leaves, without which we cannot have fine heads. Two sorts should always be sown at the same time for each successional crop; at the earliest spring sowing Snowball and Early London, next Walcheren and Early London, and for the late crops Veitch's Pearl and Autumn Giant, thus insuring and prolonging the supply from each sowing.

KIDNEY BEANS.—With these there is no special difficulty. Our supply would be taken from the June sowings in a rich soil, preference being given to Ne Plus Ultra. The plants are 6 inches apart, and some watering and mulching is requisite in parching weather.

MUSHROOMS.—These should always be included in a selection of vegetables. Amenable to culture in so many ways, the process is more a matter of expediency than of rule, if only due care be taken to have the bed about a foot thick after it is well beaten; to insert the spawn at a temperature falling from 90° to 85°, each piece of spawn being an eighth part of an ordinary Mushroom brick, and 9 inches apart in the bed; to cover if possible with pure loam fresh from a meadow; to maintain the house at an equable temperature of 55°, and to remember that the bed must be made about two months before the time when Mushrooms are required.

BRUSSELS SPROUTS.—Though these can hardly be regarded as an autumn vegetable, yet, as they are then frequently exhibited, I may mention Paragon as a distinct and handsome sort, which I had in cultivation for the first time last season, and which proved a distinct and valuable introduction. Under the ordinary treatment its sprouts were remarkably uniform in size, not large, but of the medium size, for which there is a general preference, very handsome, compact, and delicately flavoured.

POTATOES.—Only those sorts should be exhibited in which we have high quality and abundant produce in combination with full eyes and handsome form. Of such I may mention Improved Snowflake of the kidneys and Porter's Excelsior among rounds. Rich soil must be had to do full justice to them; in a poor soil they prove comparatively worthless.

CELERY.—Sturdy plants should be ready for the trenches about the middle of this month. Especial care must be taken to keep this early crop growing freely, for if it sustains a check or suffers at all from drought it will bolt to seed prematurely and be spoiled; it must, therefore, be watered regularly and frequently. In hot dry weather a thorough daily watering is necessary, and before the earthing begins drain pipes are set on end, the bottoms resting upon the soil in the trench, and the tops protruding out of the soil used for bleaching the Celery, so that water may be poured down them to the roots without risk of its lodging in the centre of the plants and causing decay. Select firm medium-sized Celery, crisp and well bleached, for exhibition, rather than that which is large, soft, and stringy, always remembering that mere size is a secondary consideration. There are several good sorts, and among the best are Major Clarke's fine Solid Red and Sandringham Dwarf White.

TURNIPS.—A late June sowing would probably afford us our supply at the end of August, but the only safe plan is to sow small successional beds of Turnips throughout summer. As soon as one crop is nicely in leaf sow another, our succession of sorts being Early Milan, Early Purple-top Munich, White and Red Strap-leaf for summer, Snowball for autumn, and Chirk Castle for winter and spring.

CARROTS AND OTHER ROOTS.—For a few handsome roots of Carrot and Parsnip, holes made in firm soil and filled with rich sandy soil is a sure and speedy way, a pinch of seed being sown at each station, and the plants thinned to one as soon as they are large enough. Of Onions take Banbury Improved, Beet Pragnell's Exhibition, and of Leeks The Lyon. Jerusalem Artichokes should be grown in very sandy soil to have them as round as a ball if required for exhibition.—EDWARD LUCKHURST.

SEASONABLE NOTES ON VINES.

IN 1863 I was called to take charge of a range of vineries, and though of course I had previously received some four years' tuition in general gardening, still all this was very different from having entire charge, even though it was under the superintend-

ence of the head gardener. It was late in the season, but the family did not require the Grapes until the shooting season, so the Vines had received but little fire, and consequently the end of May found me busy stopping and tying. All was satisfactory until news came unexpectedly that a portion of the family was coming home. Then came a lesson which I shall never forget. The laterals were trained to three wires horizontally; so far, I had attended more to the stopping not only of main laterals, but sub-laterals, and very strong they were—too strong, I knew, to tie into permanent positions; still I kept them from touching the glass, knowing that in time they would be ready for tying. The morning came, however. I was to go through the houses and tie the Vines to make them neat, though I knew they could not be done with safety. During the day the gardener showed me how he would like them done, and unfortunately he began with a Vine of Josling's St. Alban's, and this Vine was a miserable spectacle all the season, for numbers of shoots snapped off in tying and some broke in the night. The moral, of course, is, Do not tie tightly at first, just keep the shoots from the glass, also brace up with a tie any laterals that may have a tendency to bend downwards.

Since then I place great stress on stopping regularly before the Grapes flower, and so long as the leaves do not touch the glass and are otherwise secure, I generally tie when thinning. I advise all to be careful of Alicante, which is the most brittle of all late varieties, the laterals being so strong, and the young growth is often thicker than the old wood. Be content with pinching and stopping, and give bracing ties to secure doubtful laterals. My Vines 15 inches from the glass give me sufficient space. Still, had they been 18 inches I should like it better. Lady Downe's in the same house is very pliable and easy to tie, the same may be said of Alnwick Seedling. Gros Maroc is rather treacherous. All the above being grown in one house. Gros Colman shoots left till they are about to flower are easy to tie, Madresfield Court can be done sooner, Gros Guillaume is very strong and needs care; all in same house. Muscats I do not tie in permanently until I thin them.

Vines are variable in their growths in different localities. Yet I always fail to see the utility of early tying. Attend to each lateral as it requires it; do not begin at a Vine and finish it, for it is questionable if all the laterals are ready for stopping at once. I should rather say pinching, as all mine are done by thumb and finger. No hard-and-fast line can be laid down, but as a rule the top portion of the Vine is stopped first, then perhaps next day we attend to the bottom portion, leaving the centre portion of rod, which is always latest, for another day or two. It is astonishing, when the strongest laterals are pinched, how this not only strengthens them, but causes the weaker ones to push forward. In strong laterals, unless I want length for filling up, I pinch one or two leaves beyond the fruit, and give the weaker ones a joint longer.

A high forcing temperature is not required for late Grapes up to this date. Muscats are an exception. I believe that we use too much fire in the early part of the season. Vines, we all know, break best when they start naturally, therefore be gentle with fire until the Vines by their healthy growing condition tell us they are well, then gradually increase the fire. Cutting Grapes late in January caused me to be late in starting the Vines this season, with the result that they are really stronger than I ever had them, but we are now pushing them on by degrees. —STEPHEN CASTLE, *West Lynn, Norfolk.*

ANEMONES.

(Continued from page 323.)

THE second or *A. nemorosa* section of the genus contains several plants differing widely from each other in general appearance, although united by the following characters—viz., by having the seeds ovoid and tailless embedded in a mass of downy substance. The rootstock also is tuberous, varying considerably in form. This section is one of the most popular with the majority of cultivators, principally on account of the diversity of colour obtainable by the use of the varieties of *A. coronaria* and *stellata*. The members of this division, too, are widely distributed, and are found in very dissimilar positions; careful attention should therefore be given to this by the cultivator. Some of them are what are called social plants, and where found are generally growing together in large quantities, covering frequently in the case of our wild Wood Anemone several acres in many parts of the country. In the south of France, too, and the Riviera many forms of *A. stellata*, the scarlet Windflower, grow together in countless numbers and form a very distinct feature in the vernal vegetation of that district.

A. APENNINA, L.—An old and much-esteemed inhabitant of our

gardens, occasionally found in an apparently wild state in several of the southern counties, but at best a very doubtful native of this country; it, however, is found wild in abundance throughout Southern Europe. The roots are irregular tubers of a blackish colour. The root leaves are biternate. The stem leaves, produced in whorls of three, are ternate, with elongated obtuse slightly pubescent lobes. The flowers, which are freely produced in March and April, are solitary on stems 6 to 8 inches in height, of a bright sky blue, about 2 inches in diameter. This species and its varieties are not fastidious as to soil or situation, but thrive best in a light loamy soil, and are specially useful from the fact of their thriving under the shade of trees.

A. APENNINA ALBA.—A very useful white variety of the preceding, requiring the same treatment in all respects.

A. APENNINA BLANDA.—This unusually well-marked variety is considered a distinct species by many botanists; but while leaving to others more competent the task of deciding this botanical question, I can confidently assert that it has very high claims on the notice of the cultivator. The principal distinctions between it and the type are the sepals being smooth on the outside instead of being covered with hairs as in the type. The seed vessels are also each somewhat downy and tipped with a short black style. This plant is found wild in Italy, Greece, and Asia Minor; it flowers earlier than *apennina*, and also remains in bloom longer. We have several blooms still open (April 28th), the first having been seen in the first week of March. The flowers are much darker than the type, and also when well grown somewhat larger. It prefers a lighter soil and a more open situation than *A. apennina*.

A. APENNINA, FL.-PL.—A very rare form, not nearly so fine as the other varieties, but still well worth the attention of the collector of curious plants.

A. BALDENSIS, T. (syn. A. fragifera, Mur.).—A very rare and beautiful member of the genus, originally introduced into this country in 1792 from Mount Baldo. It was, however, practically lost for many years, but has been lately brought into cultivation by Messrs. Backhouse of York. The flowers, which are white, about three-quarters of an inch in diameter, on stout leafy stems 3 inches high, very much resemble those of the common Wood Anemone. The most suitable soil is a rather stiff loam, with a considerable mixture of granitic grit, and if on the rockwork a free western exposure will be found most suitable.

A. CORONARIA, L. (The Poppy Anemone).—By far the most popular species of the genus, and indeed so generally grown as to need no further description here. By successional planting this species and its varieties may be caused to bloom at all seasons, not even excepting the winter. There are several forms found in a wild state which, although not up to the florist's standard, are very effective in semi-wild situations.

A. CAROLINIANA, Walter (A. tenella, Pursh).—A somewhat robust-growing species from Carolina with white flowers, which appear about June on stems 1 to 1½ foot in height. The writer has not had much experience of this plant, but it seems to grow freely in the ordinary border.

A. NEMOROSA, L. (The Wood Anemone).—This species is so freely distributed in a wild state in this country, and, consequently, so well known, that it would not be mentioned here were it not for some of its varieties, which are so beautiful that any notes on garden Anemones in which they were omitted would be incomplete indeed. The principal forms in cultivation are *nemorosa fl.-pl.*, *rosea*, *rosea pl.*, *bracteata pl.*, and *cærulea*. Of these the three first are sufficiently distinguished by their names, and consequently require no further notice here; the two latter, however, require attention.

A. NEMOROSA CÆRULEA BRACTEATA PLENA.—In this form the double white flowers are surrounded by the enlarged leafy bracts of the involucre in such a manner as to give a decidedly frilled appearance to the blooms. It is an extremely curious and pretty variety.

A. NEMOROSA CÆRULEA (syn. Robinsoniana).—This is one of the most beautiful of spring-flowering plants, and one which should be in every collection of hardy plants however limited. The whole plant is rather larger than the type, and the flowers, which when well grown are as large as a florin, are of a beautiful pale blue, sometimes, however, much darker than usual. It is found in a wild state in several parts of England, but not in large quantities. It can be procured at nearly all hardy-plant nurseries, and will succeed well on a slightly shaded part of the rockwork, especially if planted amongst shrubs, and looks remarkably well in association with *Dodecatheons*, *Corydalis*, &c.—G. GUTHRIE.

WHAT IS AN AMATEUR?

THE question of the proper definition of an amateur is so important, and albeit a matter upon which there is so much difference of opinion, that for the behoof of all concerned some satisfactory solution should be arrived at, and all controversy on the subject settled once for all. In many societies an amateur is termed a person who does not grow plants

for sale. Now, this will allow gentlemen who employ half a dozen or more professional gardeners to enter the lists as "amateurs" against the *bonâ fide* amateur who either employs no skilled labour at all, or at the most a gardener two or three days a week. What chance would the latter have in any competition open *de jure* to amateurs, but *de facto* to everyone in the floricultural world except nurserymen? At the Crystal Palace Shows, the Exhibitions of the Auricula, Carnation and Picotee Societies, and others who might be instanced, but which are equally well known to your readers, we find exhibitors showing as amateurs who are professional gardeners, and even quasi nurserymen. Of course the rules of the particular societies permit this, and therefore the exhibitors are hardly to blame, except, perhaps, on the score of want of due appreciation of what is fair and equitable towards the rapidly growing class of amateurs.

To my mind the only true and proper definition of an amateur is a person who not only does not grow plants for sale but does not employ a gardener at all. Still, to meet the case half way, I should have no objections to seeing an amateur designated (and this is the rule in many minor societies) as a person who does not employ a gardener regularly. This latter proposition should satisfy every reasonable man, and if adopted generally would do much to allay the spirit of discontent and dissatisfaction which exists, and in no small degree amongst those who consider, and in my opinion rightly so, that under the existing definition of an amateur they are not receiving the fair and just treatment they are entitled to expect.—NORTH LONDON.

THE COMPLAINT OF THE ROSE.

Is there no more poetry in my sisterhood? Has it passed like a warm summer? Are we utterly degraded from our high and refined position? I cannot help asking, when I see such remarks about us in your last number, if Burns were with us now, instead of his sweet lyric his verses would be—

Oh! my love is like a front-rank Rose
Of a vulgar show in June.

And Hafiz—no one can write about us without bringing him in—what melancholy lines would he write!—

Oh! my love, my soul is bedewed with tears!
You are too majestic, your petals are coarse;
Your sweet scent has vanished!
You must go to the back row.

A new name is also invented for us—"pedigree Roses." Horrible title! I am fearful we are vulgarised, and must no longer be coldly civil to our lowlier sisters—Carnations, Auriculas, Pansies—who delight those who cannot, unfortunately for themselves, enjoy the sweet air and freshness of a large country garden. It is too bad! We who have listened in the calm midsummer evenings to the sweet gossip of the young and tender as well as to the bald gossip of the old and tough—we who have been chosen as the emblem of the largest empire in the world—are now degraded to being huddled up in boxes by jealous exhibitors and stared at by perspiring and crowded sightseers! Take us back to our noble gardens where we are lovingly tended; to our rustic parsonages where we are cherished as members of the family.

Even our lovers desert us. One of our largest admirers, a very big gun indeed, no longer condescends to praise us with his facile pen and witty jocosity; he no longer thinks us worthy his eloquence. Why are we thus treated? We were years and years ago as beautiful as now. This desertion is pitiful.

If we are no longer worthy the notice of the poetical minds of the day let us go back to our country homes, but do not let us become front and back ranks in a show.—VIEILLE ROSE INDIGNÉE.

ORCHID NOTES.

ODONTOGLOSSUM VEXILLARIUM IN GERMAN PEAT MOSS.—In the Orchid houses at Broomhall Field, Sheffield, the residence of B. P. Broomhead, Esq., is now to be seen a remarkable example of successful treatment of this fine Odontoglossum. A year ago the plant under notice had matured one strong growth, having been purchased the previous season as a small imported piece with one break. This growth carried three flower spikes, two of which produced eight flowers each, the third carrying seven flowers. After flowering, Mr. Walker, the gardener, repotted it in peat moss without any other compost, except a few small scraps of fibrous peat round the collar of the plant as a surfacing, and a thin dressing of sphagnum over all. Shortly afterwards the plant commenced growing and produced the remarkable number of eight strong breaks from the one growth. One of these breaks Mr. Walker took off when sufficiently advanced and potted separately. This has made a sturdy plant, which has now two flower spikes. The remaining seven growths all did well, and are now flowering with a total of fifteen spikes and eighty-four flowers. The blooms are very fine, one I measured being 3 inches in breadth by 4 inches in depth. It is not a high-coloured variety, but is very chaste and delicate, and would, I think, be preferred by many to some high-coloured forms now flowering in the same house. I examined the peat moss in which the plant is potted, and found it full of strong healthy roots.—W. K. W.

ORCHIDS AT REGENT'S PARK.—Mr. B. S. Williams, Upper Holloway, had an exceedingly beautiful display of Orchids at the Regent's Park Show yesterday, including representatives of the following species and varieties, duplicates of several being also shown:—*Aerides rubrum*, *Anguloa Clowesii*, *Calanthes Dominiana*, *masuca*, and *veratrifolia*; *Cattleyas Mendelii*, *Mossii*, *Skinnerii*, *Walkeriana*, and *Warnerii*; *Caloglyphes Massangeana* and *ocellata*; *Cymbidium eburneum*; *Cypripediums barbatum*, *barbatum Crossii*, *caudatum*, *ciliolare*, *Druryi*, *Laurencianum*, *Lowii*, *niveum*, *selligerum*, and *Swanianum*; *Dendrobiums calceolus* and *Pierardii*; *Dendrochilum latifolium*; *Laelia purpurata*; *Masdevallias Chelsoni*, *Harryana*, *Harryana lilacina*, *ignea*, *Veitchii*, and *Veitchii grandiflora*; *Mesospinidium sanguineum*; *Odontoglossums Alexandræ*, *cirrhum*, *citrosum*, and *cordatum*; *Oncidium aureum*, *concolor*, *cucullatum*, *flexuosum*, *Marshallianum*, *nigratum*, *serratum*, and *Suttonii*; *Sobralia macrantha*; *Sophranitis grandiflora*; *Trichopilia crispa*; *Vandas Dalkeith* var., *superba*, and *tricolor insignis*. The majority of these were blooming most freely, the *Cattleyas* and *Cypripediums* being especially handsome.

PHAJUS GRANDIFOLIUS.—It would be difficult to name any Orchid easier of culture or more beautiful when in flower than this *Phajus* with its giant spikes of bloom fully 4 or 5 feet high when well grown. It should be largely grown even where Orchids are not considered a feature in the garden, for we have no stove-flowering plant more attractive or useful for decoration. It is not only suitable for growing into large specimens for the exhibition hall or tent, but is equally suitable in smaller pots for home decoration, and it would be impossible to name any plant more effective in the conservatory when arranged amongst dwarfier flowering plants. Our plants are used for this, and no plants that we grow repay us better for the trouble and care devoted to them, for they are certain to bloom.

When grown for this purpose, and stood while in flower in the lower temperature of the conservatory, they receive a good rest and grow stronger and with greater freedom the following season; in fact, a good season of rest is as important with this Orchid as any other. Without rest it will soon cease growing strongly and do well, but with a season of rest it will never fail to grow with vigour, and in return produce flower spikes of great size. Plants that have occupied such positions should be turned out of their pots, and have the whole of the old soil carefully removed from amongst their roots, and new supplied. They dislike sour soil, and it is much better to repot them annually. The soil should not be elevated above the rim of their pots, but plenty of room must be left for water.

After potting they should be stood in a close moist atmosphere where the night temperature ranges about 65°, and must be shaded from strong sun. These plants should not be syringed overhead until their roots are growing freely, and until they reach this stage very little water will be needed. The material upon which they stand and their pots may be frequently syringed, but the plants must not be overwatered or their foliage is sure to be spotted, and the plants will be disfigured the whole season afterwards. Growing *Phajus* will depend very much upon the way they are watered until their pots are filling rapidly with active roots, for if supplied carelessly or too liberally before they reach this stage they seldom grow after with the same strength or vigour. When they are rooting freely and growing rapidly they require water frequently, and weak stimulants may be given every alternate time they require water.

The soil that suits these plants is good fibry peat and loam in equal portions, a seventh of cow manure (prepared by drying) passed through a fine sieve; to this may be added charcoal broken fine, meal and quarter-inch bones, and coarse sand. The pots in which they are placed should be well drained. Brown scale is their worst enemy, and should be removed by sponging.—W. B. L.

DISEASE OF VINES.

THE VINE MITE (PHYTOPTUS VITIS).

LAST autumn several correspondents of the *Journal of Horticulture* forwarded examples of Vine leaves badly diseased. In some instances the correspondents took the disease to represent a bad attack from the *Phylloxera*, and to all the writers the disease was new. As there is no mention of this particular disease in the chapter on "Diseases of Vines" in Mr. Barron's excellent book on "Vines and Vine Culture," we propose first to give our correspondents' experiences, and then a brief description and illustration of the ailment which in some instances has proved most injurious and destructive.

One of the first letters described the Vines as all crippled, and the gardener was puzzled by the novelty of the disease. Another said his Vines grew well for a time, some of them most healthily; then all at once they stopped, the stems appeared to harden, the leaves also hardened, curled, became malformed, shrivelled, and died. When the lower parts of young Vines were fresh and healthy the top and upper laterals were said to become like wire. A third account described the disease as

spreading, and an instance was given of every Vine being ruined in a house near Bristol, although under the charge of a first-rate gardener. We have also had bad accounts of the same pest from Liverpool and Frome. In one of the worst cases reported to us the Vines were received from France.

The gardeners were, and of course still are, naturally very anxious about this new state of things, and we can say from our own examination of the material forwarded to this office that it has been almost impossible to imagine Vines in a more deplorable condition than some of the specimens sent.

The general appearance of an affected Vine leaf is shown in the illustration at A, fig. 92. This leaf is by no means one of the worst, for in some examples the leaves are so distorted and ruined that at first sight it is difficult to see that they are Vine leaves at all. Our engraving shows the under side of a leaf. The dark patches are in nature pale brown, and when examined under a lens they appear as fine felted masses of cream-coloured or brownish hairs. When the leaf is turned over no such hairy patches are seen, but in their corresponding place on the top of the leaf there are numerous large green swellings, which project boldly from the upper surface. In mild cases there are but a

illustrated in the accompanying engraving, and in these secure nets it deposits eggs or, to write more correctly, buds. In the next stage the creature becomes furnished with six legs, without, however, changing its skin. In this six-legged condition the animal passes through the winter amongst the hairs of its felted nest in dead leaves. In the spring the little animal wakes up, and instead of six legs it now exhibits eight, and with its eight legs it begins to pass an active life. In this eight-legged condition the acari are found in the bark of Vines in the spring, and the bark is ascended by the arachnoids in quest of the young leaves. When the leaves are reached the mites select the lower surface, which they pierce, and there deposit their eggs. The irritation caused by the puncture appears to cause an abnormal hair-growth on the affected spot, and this dense growth of swollen leaf hairs forms a place of protection for the true eggs and the little maggots which soon emerge from them. It will be obvious from this description and the illustrations that the eggs and infant mites are in a place of great security in their position underneath, and never on the top of the Vine leaves.

The only known method of getting rid of this pest is to carefully gather together all the affected leaves and burn them. The stems of the

Fig. 92.—Disease of Vines caused by the Vine Mite, *Phytoptus vitis*.

few small disease patches, but in bad cases the leaf is more or less covered with them.

If we take a single disease pustule of the smallest size, cut it across, look at the exposed sectional surface, and magnify twenty diameters, we see it as at B; the upper surface of the leaf is represented by C C, and the lower at D D. We now notice that the swollen disease spot is really a small trough or basin filled with transparent cream-coloured or brownish hairs. A portion of the section further enlarged to fifty diameters at E better shows the nature of these swollen hairs. They are all furnished with numerous joints or stops, as is common in plant hairs.

At first this disease was supposed to be of fungus origin, and was, with many others of the same class, described in past times under the name of *Erineum*, the species belonging to the Vine being termed *E. vitis*. The name *Erineum*, given by Persoon, is derived from *erinos*, a hedgehog, in reference to the bristly appearance of the spots. Different forms have been found on the Alder, Maple, Birch, Beech, Walnut, Poplar, Rose, Lime, Apple, Pear, Bird Cherry, and other plants.

The mischief is now known to be caused by an acarus or mite of very small dimensions named *Phytoptus vitis*. The arachnoid or mite exists under four forms, first as a very small larva or maggot with two pairs of legs. This larva lies hidden in the little felted nests of hairs as

Vines should be also carefully dressed and cleaned, and in bad cases the surface of the border should be removed.

The similar affection of the Birch, commonly referred to as *Erineum betulinum*, was unusually common last year, so much so that several correspondents sent Birch leaves covered with the little crimson woolly spots to this office for an explanation of the singular appearance.

For the illustration and description of the Vine mite we are indebted to Mr. W. G. Smith.

GREENHOUSES.

MANY of your readers must have been often impressed with the great similarity in the construction of greenhouses, so far as it respects the internal appearance and arrangements. Those who have seen the one which I erected a few years ago, generally agree that it is a great improvement on the usual plan, although possibly not adapted to all positions; but I will give your readers a few particulars. I have a back wall 20 feet long, and 18 feet wide, and round this length of wall space I have carried an earth border 18 inches wide with ordinary garden edging, in which I have planted Camellias and Tacsonias, and instead of the ordinary wooden stand in the centre I have constructed a framework in blue brick carried up in tiers, starting from the level of the encaustic tile path which runs

round the house, but presenting one face only, and one side fronting from the wall. In the first border on the level with the path I have had the soil well prepared, and have planted Cheshunt Hybrid Rose, which has had sixty large flowers open at one time this spring; Lapagerias, &c., which I have trained on wirework, and which of course remain permanently in the soil. The remaining level or rather hollows of the tier I keep filled with tan, and place seasonable plants in bloom with Ferns on it, and bury the pots as far as possible. On the side and end of the house apart from the wall I have a slate slab in the ordinary way with hot-water pipes beneath. The roof is covered with the Tacsonia and other creepers, and the general appearance of the house is free from that stiff everyday style which is so common. I started on the principle of making a "garden under glass" as far as possible, and my friends tell me that I have succeeded. Perhaps some of your readers who may be contemplating the erection of a greenhouse may like to follow my example; if so, I shall be glad to give them any further information in my power. I think that for a larger house than mine the plan would answer really better.—Wm. W. BROWN, *Cotswold House, Evesham.*

FRUIT PROSPECTS.

THE unusual mild weather of the past winter and early spring months continued here until well on in April. Such weather had of course the effect of pushing the buds of Pear trees unusually forward. Fortunately, however, the frost which visited many districts was moderate here, little or no injury having been done to any fruit trees. Pears and Plums are setting good crops. Apples and Cherries are well clothed with blossom. Bush fruits in general are all looking remarkably well, with the exception of those in very exposed situations, where the embryo fruit has been blown off in large quantities. Gooseberries are a heavy crop. Peaches in unheated houses have set exceptionally heavy crops, and it will be necessary to remove about two-thirds of them. These trees, I am informed, are fifty years old or more, and are confined to borders 9 feet in breadth, including inside and outside. The young wood is consequently short and invariably well ripened, which is the sum and substance of success. Generous treatment in the form of liberal mulchings and no lack of moisture is necessary to the well-being of old trees such as those referred to.

Early Vegetables.—William I. Peas, sown at the end of November, were in bloom on May 15th, and also American Wonder, which was sown thickly in boxes in February, and planted out at the base of a sunny wall in March. The latter is in variety, which cannot be too highly valued for early work, especially in the north.—D. MACKIE, *Ayrshire.*

AN EXHIBITION OF ORCHIDS.

TRAVELLERS describe the luxuriant vegetation of tropical regions in glowing terms, and are especially eloquent when descanting upon the beauties of the epiphytal Orchids which grace the stems and branches of giant trees with rich and curious flowers; but could they by any chance witness such a display as that provided by Mr. Bull in his Chelsea nursery at the present time, their descriptive powers would be severely tested to do it justice. Orchid producing countries in all parts of the world have contributed representatives to this imposing Exhibition. Side by side are seen inhabitants of both the New and Old Worlds; flowers of enormous size in massive clusters, with others of smaller proportions in elegant light and feathery panicles appearing to float unsupported in the air; colours of almost every conceivable shade are there, from the deepest richest crimsons, brightest scarlets, and clearest yellows to the softest pink and purest white. The fresh green fronds of thousands of Adiantums and other Ferns impart an agreeable tone and foil to the brilliant tints of the Orchids, and the result is a display of wonderful magnificence.

The house devoted to this Exhibition is span-roofed, 100 feet long and 20 feet wide, with a central bed and two side stages, all being fringed with *Panicum intermedium*, a variety with much-furrowed green leaves, and long pendant shoots. In the central bed tall *Alcasias* and similar fine-foliage plants form a ridge, upon each side of which are arranged the Orchids with Ferns, not in formal banks, but free and graceful, very few stakes being employed, no glaring harsh pots being visible—nothing, indeed, to offend the eye and mar the general effect. At each end of the house are mirrors, which prolong the vista indefinitely, and the visitor who is unacquainted with this device is amazed on entering to see what appear to be interminable banks of flowers. Thousands of spikes are expanded, including a great number of rare species and varieties; but the useful and exquisitely beautiful *Odontoglossum crispum* (*Alexandrae*) is largely predominant in abundant grand varieties, no less than 1200 spikes having been counted, and their numbers are being increased daily. These are disposed throughout the house, but form a fine group at the end opposite to the entrance, where a handsome variety named *purpureum* is very noticeable for its symmetrical form and the rich purple tint suffusing the sepals, other forms having pure white blooms. *Masdevallias* are also strongly represented, nearly 600 flowers being open, including many grand varieties of the *M. ignea* and *M. Harryana* types. Of the latter *acanthifolia* and *magnifica* are very handsome; but the brightest of all is one named *Meteor*, which is of a glowing crimson scarlet unexcelled in the genus.

Cattleyas are exceedingly rich and imposing; about 150 flowers of *C. Mendelli* are expanded of many new and magnificent varieties. *C. labiata* is largely represented, the variety *brilliantissima* justifying its name by its wonderful colour; the chaste *C. maxima*, *C. Sanderiana*,

really beautiful, by far the finest variety we have seen, and scores of others. Another feature is the charming bank of *Odontoglossum vexillarium* facing the entrance to the house, where some dozens of plants are associated with *Masdevallias*. The former are much diversified, the flowers varying from pure white to the deep tints of roseum and rubrum. *Album marginatum* is peculiar but pretty, the sepals and petals edged with white; tricolor having crimson, white, and yellow flowers. *Cymbidium Lowianum* and the dark-lipped variety *atro-purpureum* is in fine condition, a total of nearly twenty spikes being expanded, some exceedingly long. *Oncidiums* contribute largely to the beauty of the Exhibition, *O. Marshallianum* being remarkably fine, one plant with two panicles bearing 128 of its grand golden blooms.

These only indicate the general features of the show, for scores of highly meritorious novelties might be enumerated. The following may, however, be mentioned as being in flower:—*Lycaste Skinneri* and its valuable variety *alba*, *Epidendrum rhizophorum*, *Sobralia macrantha*, *Lycaste aromatica*, *Cypripedium laevigatum*, *C. ciliolare*, *C. Stonei*, *Oncidium concolor* in great abundance, *Calanthe Dominii*, *Oncidium phymatochilum*, *O. citrosum* and the lovely variety *carneum*; *Odontoglossum Ruckerianum*, *O. Wilckeanum albens* (a lovely variety, white or white ground colour), the much-famed *O. mulus*, the striking *O. hystrix*, *O. triumphans*, *O. gloriosum* and variety *niveum*, with many other *Masdevallias*, *Deadrobiums*, and *Epidendrums* which cannot now be particularised.

THE announcement in several daily papers of the DEATH OF MR. T. CRANSTON OF HEREFORD caused a rumour to be spread abroad to the effect that it was Mr. John Cranston of the King's Acre Nurseries. On inquiry, however, we find that the deceased gentleman was Mr. Thomas Cranston of Pyon House, brother of the above, and very greatly respected in the district. He was proceeding alone in a dog cart to visit his farm at Newton Dillwyn, when it appears that in driving down a sharp bank a pin in one of the shafts gave way, throwing Mr. Cranston out and occasioning such injuries that he died shortly afterwards. The *Hereford Times*, in referring to the accident, remarks:—"The news of the death of this well-known and greatly respected gentleman has thrown quite a gloom over the whole district. No man was more highly honoured or held in greater esteem by all classes than Mr. Cranston, whose high and sterling character, uniform hospitality, and great kindness of heart were displayed in endless ways, endearing him to all who knew him, and winning the good opinion of all around him." We are requested to add the following note from a correspondent who is engaged in the King's Acre Nurseries:—"We are receiving no end of telegrams and letters respecting the above sad occurrence. We (the *employés*, one and all), are truly thankful that our kind employer is still spared to us, and trust he may be for many years. I assure you those who know him best love him most."

— THE NATIONAL ROSE SOCIETY'S annual report for the past season, with schedule of classes and shows for the present year, is now to hand. It gives the names and addresses of the members, a list of the affiliated societies, the names of the winners of the Society's medals in 1883, the financial report and full schedules of the Exhibitions to be held at South Kensington on July 1st, at Salisbury on July 9th, and at Manchester on July 19th. With regard to the Kensington Show it may be remarked that all exhibits will be required to be ready for the Judges at 10 30 A.M., and the entrance for exhibitors will be at the back of the conservatory on the west side of the Royal Albert Hall. A new regulation is also appended, which states that "none but members of the National Rose Society will be allowed to compete at this Exhibition."

— TOBACCO JUICE OR TOBACCO WATER.—The public are often making inquiries as to how and where this juice can be procured (under the name of the London Tobacco Juice), very few knowing that a grant from the Hon. Board of Customs was allowed to Messrs. Corry & Soper of Shad Thames, London, S.E., in the year 1866, for the purpose of extracting the juice from leaf tobacco for horticultural purposes, entirely free of duty, thereby enabling the public to get a strong article containing about 40 cwt. of leaf tobacco to every gallon for the sum of 2s. 6d., being a great saving on the ordinary tobacco water

obtained from the tobacco manufacturers, as it may be diluted with eight to ten parts of water with the best results, thereby being a great saving not only in cost but in carriage. We believe Messrs. Corry and Soper are the only makers of this article in London, and it may be obtained through the seed trade generally.

— THE LUDLOW ROSE SHOW is announced to be held on Tuesday, July 8th.

— AURICULA WITH A PRIMROSE HABIT.—Mr. W. Dixon, an amateur in Walsall, has amongst some seedling Auriculas a self with a very clear white paste, but producing one pip only on a stem as in the Primrose; and asks "if any other Auricula growers have found this to be a common occurrence, or is it unusual?"

— "F. K. B." writes:—"Two BLUE FLOWERS unnamed by 'Conservative Rose' have suggested themselves to me—*Omphalodes verna* for early spring blooming, and Borage. This latter may be too much of a wild flower for her purpose, but it is a beautiful blue colour."

— THE TOOTING HORTICULTURAL SOCIETY announce their third annual Exhibition for June 25th and 26th, which will be held in the Vestry Hall, Broadway, Tooting. Prizes are offered in eighty-two classes for plants, flowers, fruit, and vegetables. The Chrysanthemum Show will also be held in the Vestry Hall, November 18th and 19th, when, in addition to the numerous classes for Chrysanthemums, prizes are also offered for miscellaneous plants, fruit, and vegetables.

— MR. WM. HORLEY, Toddington, Beds, sends us some trusses of PANTALON POLYANTHUS SEEDLINGS, of which he states he "has had a fine display, having bloomed several hundred seedlings, and fully 75 per cent. being hose-in-hose." The blooms received were exceedingly distinct and pretty, most varied in colours, several shades of crimson, maroon, and red being represented, some being margined, laced, or streaked with white. The strain is an extremely meritorious one, for such bright and varied flowers are invaluable in the spring.

— "R. P. B." sends us blooms of ROSE REINE MARIE HENRIETTE, which he describes as "a grand variety worthy of much praise," in which we heartily concur. It is, indeed, a magnificent Rose, very broad in the petal, rich rosy crimson, full, of great substance, but does not possess much fragrance. It is vigorous in habit and free in flowering.

— THE forty-ninth ordinary meeting of the ESSEX FIELD CLUB will be held at the head quarters, 3, St. John's Terrace, Buckhurst Hill, on Saturday, May 24th, 1884, at seven o'clock. The following communications are promised:—

I.—"Report on the Flowering Plants Growing in the Neighbourhood of Colchester." By J. C. Shenstone, F.R.M.S., &c. II.—"Progress of the Report on the Recent Earthquake Shock in Essex." By Raphael Meldola, F.R.A.S., &c., and W. White. III.—"On the Earth Subsidence at Lexden, near Colchester, in 1861." By T. V. Holmes, F.G.S., M.A.I. IV.—"On the Occurrence of the Rhizopod (*Clathrulina elegans*) in Essex." By C. Thomas, F.G.S., F.R.M.S.

A series of photographs illustrating the effects of the earthquake will probably be exhibited. Field meetings will be held on June 2nd at South Weald, and on June 21st in Epping Forest.

— "W. D. W." sends the following respecting a RARE PLANT:—"A gardener, in his own estimation a bright and shining light, recently sent to a lady in a midland town some tubers of *Tropæolum tuberosum* with the following name and description:—'Podefolium, or Potato Climations. Quit new. I thought would Look very nice to Run over the Thorn Edge in front of Window.' Truly a little learning is a dangerous thing."

— THE above reminds us of an occurrence at a recent provincial exhibition, in which an exhibitor displayed a rather astounding knowledge of PLANT RELATIONSHIP. A class was provided for six Lycopodiums, thereby meaning Selaginellas, and in one collection a specimen of *Nertera depressa* was included. That the intentions of the exhibitor were honest was manifested by the fact that a label bearing the name was placed in the pan, and this circumstance rendered it the more remarkable that the Judges should have awarded it a prize; the mistake was, however, subsequently discovered and rectified. Several peculiar names were attached to the other plants, as, for example, *Aspidium alatum* to *Selaginella Kraussiana*, and *Lycopodium argentea* to *S. uncinata*, so that it was evident the exhibitor's notions of plant names were, to say the least, somewhat mixed.

— MESSRS. STEVENS & WILLIAMS, Brierley Hill Glass Works, Staffordshire, send us a sample HYACINTH GLASS of an extremely

elegant shape and novel colour. It is about 6 inches high, oval, contracted near the mouth, and then expanded into a neat undulated rim, to which is affixed the brass support for holding the bulb and spike in position. They are of various colours—rose, blue, violet, ivory white, and amber, the white and amber being very pleasing.

— THE ROYAL HORTICULTURAL SOCIETY OF IRELAND held an attractive Show in Mr. Guinness's grounds, Dublin, on Thursday last, the following being the principal exhibits. The Society's cup for twelve exotics was won by Wm. Jameson, Esq., with a superb collection, amongst which was a splendid specimen of *Cycas revoluta*. The Society's cup for nine pot Roses was won easily by Charles Strong King, Esq., with a very fine collection. The six exotic Ferns shown by L. G. Watson, Esq., were of extraordinary beauty, as were the six Lycopods of Phineas Riall, Esq., amongst them being a plant of *Selaginella lepidophylla*, well furnished and of remarkable verdure. Some of the most lovely flowers in the Exhibition were the nine first-prize Gloxinias from Richard Pim, Esq. The Azaleas of George M'Master, Esq., and the Rhododendrons of W. J. Perry, Esq., made a magnificent display, as did the Pelargoniums of Richard Pim and W. J. Perry, Esqrs., who divided first honours in this class. A. F. de G. Cusack, Esq., took first prize for Calceolarias, showing some plants of considerable merit. The first prize for Tree Ferns was awarded to C. S. King, Esq., for a fine specimen of *Dicksonia antarctica*. In cut Roses the first prize for twenty-four blooms, exclusive of *Maréchal Niel*, was won by the Rev. F. Tymons with a very good collection; C. S. King, Esq., taking first prize for *Maréchal Niel* with twenty-four magnificent blooms; the second-prize collection (Phineas Riall, Esq.) also possessing great merit. In the extra classes, and amongst exhibits not intended for competition, were a very interesting collection of choice and rare plants kindly sent from Glasnevin by the Curator of the Botanic Gardens, Mr. Moore; a most extensive and varied collection of ornamental stove and greenhouse plants from Messrs. Henderson and Son, Fortfield Nurseries, Templeogue; a choice and beautiful group, including some of the finest varieties of Show Auriculas, forwarded from Riverstown, Nenagh, by J. T. Poe, Esq.; and a very extensive collection of the same forwarded from his nurseries, Ballybrack, Co. Dublin, by Mr. Kavanagh. A stand of *Tulipa Gesneriana*, remarkable for their brilliant colour, from Rev. Frederick Tymons, was much admired. Stand of choice tuberous Begonias, from the gardens of the Earl of Portarlington, commended. In the florists' department a magnificent stand of no less than forty-eight choice Tea Roses, and an equally fine stand of the newest and best varieties of Zonal Pelargoniums, was forwarded from the Lough Nurseries, Cork, by the proprietor, Mr. Hartland.

ALEYRODES VAPORARIORUM.

I HAVE this day sent off, per parcel post, a small box containing a glass tube enclosing a Tomato leaf infested with a small white insect, which is causing me considerable trouble, for which I have tried to remove by using Fowler's & Keel's insecticide and Fir-tree oil, after having smoked twice with tobacco paper and Laurel leaves. I have syringed the Tomatoes with the above and dipped them as well as I could, all to no use. I should be thankful for any information that can be given to enable me to get rid of the pest, as it is doing considerable mischief. Also, I should be glad to have its name as well, if possible.—A TWELVE-YEARS SUBSCRIBER.

[The name of the insect is given above, it is also popularly known as the "Holy Ghost" insect. It limits its attacks to a few kinds of plants, of which the Tomato is one. We shall be glad if any of our readers can supply the information that is needed by our correspondent.]

GRAPES ON VINERY WALLS.

IN reply to "Journeyman" (page 382) the back wall of the vinery is 11 feet high. The Vines were Black Hamburgs, two-year-old canes, short-jointed, and grown in large pots. They were planted in the border, and trained on the wall. The number of bunches were nine and eleven on each side, averaging about three-quarters of a pound. They were very regular, and the foliage round and thick; the fruit very sweet and sugary.

They had copious supplies of water and urine, with strong soot water. As soon as the bunches were thinned and colouring well, none of my Vines received a drop of water from the syringe from starting till the Grapes were cut last year, but many hundred gallons were poured inside the vinery. I sent a box of fruit to the Editor last autumn, but it miscarried. It contained a fair specimen of the above, with foliage.—J. E. W.

STRAWBERRIES AND CROCUS GRASS.—Strawberries in wet weather are very liable to be soiled and splashed if something is not placed

beneath the berries to raise them from the ground. Hay and straw are, like other similar materials, open to the objections that they are liable to decompose and to harbour slugs. At Minella to-day I saw a new use for Crocus grass as a substitute for the hay or straw or other material placed around each Strawberry plant. Cartloads are cut off at this season in large establishments, and, I venture to say, in no better way could it be utilised. This Crocus grass is hard and wiry, and will last as I suggest for a long time.—W. J. MURPHY, *Colonel*.

SPRING DIGGING.

THE busy season for gardeners has come round once more. In the kitchen garden especially all is, or should be, actively going on, as any neglect or delay at this time will bring its punishment late in the season. Stirring the ground between growing crops has been advised times without number in gardening periodicals, and this year it will be more important than at any time in my recollection. The extraordinary absence of frost during winter and of drying winds in March, has left all heavy soils in poor condition for the reception of seed. For my own part it has been a not altogether unmixed evil, as I am determined from this time to dig no heavy soils until cropping. I should have been in a better position with kitchen garden work had I taken the advice which Mr. W. Taylor gave in the Journal some years ago, to discontinue autumn digging; but never knowing long beforehand the amount of forest tree planting I may be called upon to do, I have been in the habit of having digging done early in autumn or winter, so as to be ready for any emergency. In some years the plan has worked well, but this year it was nearly impossible to get the land into good condition. The time spent in preparing for Potatoes and all early crops was more than double what it should have been. Frequently stirring the soil between growing crops must be resorted to at all opportunities, or the result will be poor crops on all heavy land. Immediately the plants appear above ground, forking between the rows will be done two or three times in dry weather, and after that the Dutch hoe will be employed, and by these means I hope to bring the soil into good condition.—T. A.

SEASONABLE NOTES ON FLORISTS' FLOWERS.

AURICULAS.—As I have already said, my notes from henceforth on these and other florists' flowers will not be from the exhibitor's point of view, but from that of the general grower who is contented from one cause or another to keep away from the struggles of the exhibition tent, and to be satisfied with his flowers at home. I hope I shall not fall into the error of too highly estimating them, for I shall have the corrective of seeing the splendid specimens of culture we can see now-a-days. How often have we heard, "Oh, I have much better than those at home?" How often has the salmon which got away with the fly and line been by far the finest fish seen all the day, and the fox that got away the most splendid fellow for a run that had been seen for some time? and I shall, I hope, therefore know how to moderate my expressions: but I have not for some years had a finer bloom of Auriculas than this season. I dare say my plants would have been nowhere alongside of Mr. Horner's or Mr. Douglas's, but even to my eye they were good, and yet I see woolly aphides crowding around the crown. The plants have now nearly finished their blooming, and I shall next week remove them to their summer quarters under a hedge facing the north. I shall probably commence repotting at the end of the month, and as my collection is small it will not take very long. I am quite sure the simpler the compost, provided it is good, the better—three parts turfy loam and one part cowdung, with a little leaf mould and charcoal, I think about the best. I think the size of pots not a matter of any great importance. That they will do well in small pots is unquestionable, but that most successful grower, Mr. Woodhead, was accustomed to use large pots; but, then, he always put a large quantity of drainage, so that it came to nearly the same thing, and if 5-inch pots are used this will be necessary. A longer experience of glazed pots confirms my preference for them. The plants look better in them, and do not require so much water in the winter months, while the plants are quite as vigorous as in the ordinary unglazed pots. I believe in firm potting, and when there is any sign of woolly aphids the roots should be well washed in soap and water or in a weak solution of Fir-tree oil. As aphides are abundant this year I have given my Auricula pit a good smoking, and the plants will all be gone over with hand, dead leaves and stems picked off, and the surface stirred before they are moved to their summer quarters.

CARNATIONS AND PICOTEES.—I never planted out a more healthy set of these plants than this year, but they have had a hard time of it since then. They had not been coddled during the winter, and had been stood out of doors for some time before they were planted; but those cold frosty nights (although with us the frost was not nearly so severe as in some parts), the easterly winds, and hot suns injured them very much and checked their growth. If stakes have not already been placed to them it should be done at once, and the flowering shoots tied to them. The surface of the ground ought to be stirred, as nothing conduces more to the well-doing of the plants than the use of the hoe or fork.

PANSIES.—I have had a good collection of these in flower in pots, and certainly most remunerative they are for any care bestowed on them, especially the Fancies, some new ones of Mr. Hooper's of Bath being specially noticeable. They will soon have done flowering, and will then be turned out of their pots into a cool part of the garden, which I find difficult to get, and then the plants will be spread out and some light

compost shaken in amongst them. There will be, when the time for taking up comes, plenty of young plants by dividing the roots, and these I have found to do quite as well as from cuttings, and a great deal of trouble is thereby spared.

GLADIOLI.—These are late in coming up with me this year—I suppose owing to the long-continued dry weather; and in a note received this morning from Fontainebleau, Mons. Soullard says that he has only just completed the planting of his bulbs. Nothing will require to be done to the beds now except keeping them clear of weeds.

ROSES.—One hardly likes to write of these as florists' flowers, but their *clientèle* is far more numerous than that of all other florists' flowers put together, and many are the inquiries now made about their prospects. Some write in despair that they are so backward, that they cannot possibly have any blooms in time for the exhibitions, &c. It has been a very extraordinary season, and will be the means, I think, of making many converts to the system of late pruning, as I see it has already done with many of your correspondents. Mine were not pruned until late in April. There were then flower buds on many of the stems and the plants quite green. I did not find that cutting them in this condition caused bleeding to any appreciable degree, and since then they have made good shoots, and I have no doubt that they will be quite up to their usual vigour when the "time of Roses" comes. Let the hoe be well used amongst them; it is as good as manure to them. Those who exhibit have their beds all mulched now. I have had the mulching on my beds all turned in for appearance sake, as I do not exhibit. Should this dry weather continue watering with weak liquid manure will be necessary.—D., *Deal*.

CACTACEOUS PLANTS.

(Continued from page 342.)

DISCOCACTUS, *Pfeiffer*.

THE two or three species which have been assigned the generic name of Discocactus are amongst the least interesting members of the whole family, and certainly their horticultural value is small. They are dwarf and semi-globose in form, very suggestive of an Echinocactus in appearance, and some writers have thought that the two genera were not sufficiently distinct to be separated. It must not, however, be confounded with the Discocactus or Disisoeactus biformis of Lindley, which is a totally different plant, now referred to Phyllocactus. The principal characters adopted by Hooker and Bentham are the following:—Calyx and tube extending beyond the ovary, slender; base naked, smooth; lobes indefinite, exterior reflexed, interior larger. Petals in two series, spreading, interior smaller. Stamens indefinite; filaments adnate to the tube of the calyx, interior longer; anthers small. Stem depressed, ribbed; ribs few. Flower usually solitary from the apex of the plant, and fragrant.

The species are natives of Brazil and the West Indies, inhabiting dry sandy regions, and are found rather difficult of cultivation, and at the present time I do not know one collection which contains living plants. They require a warm sunny position and great care in supplying water, as the slightest excess results in the death of the plants.

D. INSIGNIS, *Pfeiffer*.—This is the best known, and is chiefly noteworthy for the fact that its flowers possess an extremely agreeable fragrance, which has been compared to that of Orange blossom. The stem is semi-globose, with nine or ten obtuse ridges, and a crown of white wool-like substance, from which are produced the long and slender flowers, having the sepals pink, and the petals white or bluish-tinted. D. alteolens has the stem of a much darker green colour, and flowers with a less pleasing odour.

CEREUS, *Haworth*.

(The Torch Cactus.)

Leaving the globose or tubercled Cactæe represented by those previously described, we find in Cereus a greatly different mode of growth the stem being greatly elongated, usually of small diameter in proportion to its height, frequently much branched, but bearing parallel ridges from apex to base, upon which are arranged bundles of spines, as in other genera. In height these plants are the giants of their family, some forming in the native habitats enormous columns 40 to 60 feet high, while even in cultivation it is not uncommon to find specimens 15 to 20 feet in height. Some are very rapid growers, and make large plants in a few years. Others, again, are so slow in growth that a dozen years seem to make no appreciable difference in their size. There are, however, two very distinct sections or groups of species of the true Cereus, which differ considerably in habit; one species being distinguished by their erect rigid stems, and the other by the procumbent or trailing slender stems. The plants included in both bear handsome and abundant flowers, but the ereeping or trailing forms are the most beautiful, and contain most of the much-famed Night-flowering Cactæe. The genus Cereus, however, as now constituted includes a large number of plants which were formerly assigned to other genera, but which modern botanists consider are entitled to no higher rank than sub-genera. Under the name of Cereus are therefore arranged over two hundred species, natives of tropical America, the West Indies, and Galapagos Islands, from regions differing considerably in temperature, but generally agreeing in the peculiar dry sandy or rocky nature of the soil they inhabit.

Hooker and Bentham thus characterise the genus and adopt the following subgenera as pointed out by Dr. Engelmann:—Calyx tube produced beyond the ovary; lobes numerous, exterior scale-like, interior elongate, spirally imbricated. Petals indefinite, larger than the calyx lobes,

spreading. Stamens numerous; filaments adnate to the base of the calyx, the inner free. Ovary exserted, scaly. Style filiform. Stigmas five to indefinite. Fruit scaly or tuberculated. Flowers lateral, often nocturnal.

Echinocereus.—Calyx tube short, sub-campanulate. Stigmas thick, green. Seed tuberculated. Stem dwarf, often sub-globose.

Eucereus.—Calyx tube long. Stigmas pale. Seeds smooth, rarely rugose. Stem tall. Spines in flower bearing and sterile parts of the plant not different.

Lepidocereus.—Calyx tube short, scaly; lobes few. Petals fleshy. Stigmas pale. Seeds smooth. Stem tall. Spines of floriferous or sterile fascicles alike.

Pilocereus.—Calyx tube short, scaly; lobes few. Stigmas pale. Seeds smooth. Stem tall. Sterile and floriferous fascicles dissimilar.

Echinopsis.—Calyx tube elongate, downy; lobes numerous. Stamens

for grafting other Cactæ upon has already been noted, and it need only be added that almost any species is suitable for the purpose provided it be not of too slow growth.

SELECT SPECIES.

It will be convenient in considering these to take the true *Cereus* first.

CEREUS PERUVIANUS, Pfeiffer.—Under various names this *Cereus* has been known to botanists and grown in European gardens for upwards of 150 years, and it is therefore the most familiar example of the columnar species. The titles by which it has been designated, such as pentagonus, hexagonus, and heptagonus, refer to the number of ridges or angles upon the stem, and owing to these varying considerably the same species in different stages has received the respective names. *C. pentagonus* of Haworth has been regarded as distinct from *C. peruvianus*, but there appears to be little doubt that in a broad sense all that have been described under these names are simply variations of one type represented by *C. peruvianus*, which is a native of many districts in tropical America. There with *C. giganteus* and other allied species it forms a remarkable feature, the tall rigid stems being sometimes freely branched in candelabra-like manner, and producing at certain seasons abundance of beautiful flowers.

In cultivation this *Cereus* grows rapidly, and soon, if unrestricted, attains a height of from 12 to 20 feet, a few specimens being seen as much as 30 feet high. Probably the most remarkable in England are those in Mr. Major's collection at Cromwell House, Croydon, of which an engraving is given in fig. 93, prepared from a photograph very kindly furnished by Mr. Major. The original plant (the central one in the figure) was bought in Holland in 1852; but by cutting down the stem at intervals a family of fine specimens has been obtained, some of which are equally as large as the parent. The old stem has two branches, each 4 feet high, three others 6 feet high, and a small one 18 inches in height. One straight unbranched stem, the first top taken off, is 13 feet high. The next cutting developed into a fine plant, now in Mr. Peacock's collection, about 14 feet high, with several branches, and which last year had as many as thirty-six flowers. The fourth plant is 8 feet high, with two branches; the fifth, which has been topped, has two branches 11 feet high, two 6½ feet high, and one 18 inches in height. It will thus be seen that one plant has produced a total length of stem, counting all the branches, of 80 or 90 feet, of an average diameter of 5 inches, in about thirty years. The Cromwell House collection includes many rare and beautiful Cactaceous plants; but this group of *Cereus* is undoubtedly the most remarkable of all.

Plants of moderate age generally have the stem from 3 to 6 inches in diameter with narrow ridges 1 to 1½ inch deep and 2 inches apart, very distinctly marked in the young growth, but on older stems the ridges are nearly lost. The clusters are 1 inch apart, containing six to eight brownish spines half to 1 inch long on a small brown tuft of wool-like substance, which is sometimes scarcely perceptible. The stem is usually deep green, but the young growth occasionally assumes a glaucous blue colour almost as strongly marked as in *C. Jamacara*. The flowers are white or sometimes tinged with red, 4 to 6 inches in diameter, and are borne freely during the summer months on the upper portion of the stem or branches.

C. PERUVIANUS MONSTROSUS.—This is a peculiar variety of the fasciated or contorted type so frequent in these plants. The substance of the stem is most strangely twisted and irregular in form, grotesque in the extreme, and not bearing the slightest resemblance to the species except in the flowers. Specimens 4 or 5 feet high are sometimes seen in cultivation, and one of the largest is in Mr. Boller's collection. A smaller form of this variety named *minor* is also grown, and rarely exceeds 6 or 8 inches in height, peculiarly contorted, but not so fasciated as the other.—L. CASTLE.

(To be continued.)

VINE GROWTH.

IN last week's Journal it is stated by "A Kitchen Gardener" that young Vines that are stopped "as soon as the top of the house has been reached, and are never allowed to go further, become very much thicker on the part which will bear the fruit than they would do if allowed to grow unchecked"—as some growers allow their Vines to do—permitting the shoots to grow down the back wall as your correspondent describes. I agree with "A Kitchen Gardener" that it is best to stop the rods at a reasonable height, but it is certainly not the case that Vines so stopped grow thicker in the stem than those which are allowed to extend. The thickness of the trunk of any young or old Vine is exactly and invariably in proportion to the amount of top growth allowed; and the fact is easily explained on physiological principles, well understood and acted upon by all intelligent workmen in thinning plantations. The Vine, however, shows this sooner than most other plants, and if your correspondent will grow two Vine rods of equal strength from the same Vine, and stop one and let the other grow, he will soon prove it to his own satisfaction, for the one that is stopped will be much the slenderest cane. I could show many striking examples of this here on young and old Vines, but the fact is admitted by growers generally.

"A Kitchen Gardener" also states that the practice of leaving Vine rods 12 feet long the first year and fruiting them, instead of cutting them back in the old way, is associated in his mind with Mr. Pearson of Chilwell, whose experiments were conducted, he says, long prior to those of present Grape-growers. I know Mr. Pearson's Vines, and was under the impression that the whole of the Vines at Chilwell at the period referred to were grown on the cutting-back system. I have also read Mr. Pearson's writings and the book on the Vine published by him or the firm after the date referred to by "Kitchen Gardener," and to the best of my recollection it contains no instructions or allusions to the point raised by "Kitchen Gardener;" so that if Mr. Pearson practised the system he has not thought it worth while to recommend it to others.—NON-BELIEVER.

ESTABLISHING ROOKS.—My employers having some young rooks, they are very anxious to get them to build in our park. The trees are princi-

Fig. 93.—*Cereus peruvianus* at Cromwell House.

in two series; the exterior adnate to the calyx tube, inner free. Fruit scaly. Stem depressed, ribbed, globose, or cylindrical.

Culture.—In so large a genus there must necessarily be some difference of cultural requirements, but this chiefly refers to the temperature, and if the region and elevation at which the plant is found is known there will be comparatively little difficulty in ensuring its success. Most of the true *Cereus* (the *Eucereus* of the above table) need a tropical temperature, with similar soil to other genera, though as a rule the strong-growing species can be safely encouraged with a little well-decayed manure if necessary. The trailing sorts need very little rooting material, and some indeed, as *C. grandiflorus* and its allies, obtain sufficient nutriment by their stem roots alone when upon a suitable wall or trellis. They can all be readily propagated by cuttings of the growth, and even large portions of the stem will root if separated from the parent and placed in dry soil. So readily are roots produced that in some parts of tropical America live fences are formed by placing portions of the stems in closely together, and it is said that they rarely fail. The use of certain species as stocks

pally Oak, and some of them are very large. I have been asked about them building and the food they required, but as I know nothing about them I thought I would write to the *Journal of Horticulture*. I have looked up the back parts for the last two years, but I cannot see anything about them. Can any reader kindly let me know the best way to keep them and how to look after them so as to induce them to build on the place?—A. McK.

BATH SPRING SHOW.

MAY 14TH.

ANOTHER most successful Exhibition was held in the Sydney Gardens, than which no more beautiful or convenient site could well be selected. The weather being favourable, crowds of visitors thronged the Exhibition, and apparently fully appreciated the rich floral and musical treat provided by the energy of the Committee of the Bath Floral Fêtes, of which Messrs. R. King and B. Pearson are respectively Chairman and Honorary Secretary. The majority of the classes were well filled, four tents, one very large, being devoted to the various exhibits.

AZALEAS.

These are invariably well shown at Bath, and on this occasion the many specimens, large and small, were at their best. The groups were alternated with the fine-foliaged plants, and the effect as viewed from the ends of the long tents was grand. With twelve specimens a local grower, Mr. W. T. Biggs, gardener to J. C. Hurle, Esq., Brislington, took the lead, and was followed by Mr. J. Cypher, Cheltenham, the third prize going to Mr. C. H. Keel, gardener to Colonel Landon. The first-prize specimens were large closely trained pyramids, some of the best being Duc de Nassau, Stella, Sir C. Napier, Fascination, Model, and Beauty of Surrey. Mr. Cypher's were large, well-flowered, globular specimens, Mr. Keel's being irregular and beautifully flowered pyramids. In the class for nine specimens Mr. W. Long, gardener to C. Gardiner, Esq., was first with magnificent plants of such varieties as Roi d'Holland, Model, Magnet, Souvenir du Prince Albert, Iveryana, and The Bride. Mr. W. C. Drummond was a creditable second. Mrs. West had the best six specimens, and Messrs. Long and W. C. Drummond were successful in other classes for Azaleas.

STOVE AND GREENHOUSE FLOWERING PLANTS.

With twelve specimens Mr. Cypher was an easy first; Messrs. Long, J. F. Mould, Pewsey, and E. Tudgey, Waltham Cross, taking the remaining prizes in the order named. Mr. Cypher's grand group included a magnificent specimen *Erica depressa*, *E. Lindleyana*, *E. Cavendishiana* being also large and well flowered. *Anthurium Schertzerianum* Wardii with twelve fine spathes; *A. Schertzerianum*; immense specimens of *Azaleas Cedro Nulli* and Mrs. Fry; *Pimelea Hendersonii* and *P. spectabilis*; *Hedera tulipifera* and *Aphelaxis macrantha purpurea*, all in excellent condition. Mr. Long had among others fine specimens of *Ixora Prince of Orange*, *I. Williamsii*, *Rhododendron Gibsonii*, *Hedera tulipifera*, and *Azalea Model*. Messrs. Mould's and Tudgey's plants were well flowered, but were generally smaller than the above-named. The best nine plants were staged by Mr. W. F. Biggs, and included highly creditable examples of *Aphelaxis macrantha purpurea*, *Genetyllis Hookerii*, *Ixora Prince of Orange*, and *Erica Cavendishii*. Mr. C. H. Keel was a good second, the third prize going to Mr. W. C. Drummond. With six plants Mr. W. J. Mould, gardener to E. E. Bryant, Esq., was first with moderate-sized well-flowered specimens of *Bougainvillea glabra*, *Genetyllis Hookerii*, *Dracophyllum gracile*, *Pimelea spectabilis*, *Clerodendron Balfourianum*, and *Genetyllis tulipifera*. Mr. G. Tucker, gardener to Major W. P. Clarke, Trowbridge, followed, his groups including a fine specimen of *Anthurium Schertzerianum Veitchii*; the third prize being well won by Mr. H. Jones, gardener to General Doherty. In the single specimen class Mr. W. Long was adjudged the first prize for a good plant of *Ixora Williamsii*, the more valuable specimen of *Anthurium Schertzerianum densifolium* bearing grand foliage and twenty large spathes staged by Mr. Cypher gaining the second position. *Ericas* were shown in goodly numbers, and included many meritorious specimens. Mr. Cypher had the best six, Mr. W. Long being a good second. Messrs. J. F. Mould, W. J. Mould, and W. F. Biggs were also successful exhibitors of *Ericas*.

FINE-FOLIAGED PLANTS.

The best sixteen specimens were staged by Mr. Cypher, among these being fine plants of *Kentia australis*, *K. Fosteriana*, *Cocos Weddelliana*, *Pritchardia pacifica*, *Dasyllirion acrotrichum* and *Phormium tenax variegatum*. Mr. J. F. Mould was placed second, his group including *Gleichenia rupestris*, *Cocos Weddelliana*, *Dracæna Goldiana*, and *Croton Johannis* in good condition. Mr. W. J. Mould had a good group, and secured the third prize. Several groups of Ferns were arranged, *Adiantums*, *Davallias*, *Gymnogrammas* predominating, and of these the most successful exhibitors were Mr. J. Coke, gardener to A. P. Stancombe, Esq., Trowbridge, and Messrs. W. J. Mould, G. Tucker, H. Jones, and W. C. Drummond.

ORCHIDS.

These are not usually well shown at Bath, but on this occasion there were several competitors, and a few choice sorts included. Mr. Cypher had the best six varieties, these consisting of a good pan of the lovely *Cypripedium niveum*, *Dendrobium nobile pendulum* in good condition, *Masdevallia Lindeni*, *Cattleya Mendeli*, *Odontoglossum Halli*, and a good pot of *Dendrobium Jamesianum*. The second prize was awarded to Mr. F. Perry, gardener to H. C. Cruger Miles, Esq., Bristol, who had *Cypripedium caudatum roseum*, *Cymbidium Lowianum*, *Lælia cinnabarina*, *Odontoglossum Pescatorei*, *Cypripedium Boxalli*, and a good form of *Masdevallia Lindeni*, all in good condition. Mr. W. J. Mould was third, his best being *Dendrobium thyrsiflorum*, *Odontoglossum Alexandræ*, and *Cattleya Mossiæ*. Mr. Cypher also won the first prize for a new or rare plant with the beautiful and distinct *Cypripedium Robelianum*, bearing six flowers. Mr. W. J. Mould followed with *Odontoglossum radiatum*.

ROSES AND PELARGONIUMS.

One tent was filled principally with the numerous pot plants of these. The best nine varieties of Roses were staged by Mr. J. F. Mould, and

included were good specimens of Dupuy Jamain, Charles Lawson, Etienne Levet, Abel Grand, and Madame Lacharme. Mr. M. Cole, gardener to R. B. Cater, Esq., Bath, was a good second, his group comprising well-flowered plants of *Devoniensis* and Madame Willermoz, Baronne de Rothschild and Madame Gabriel Luizet. Mr. A. W. Southard, gardener to F. J. Walker, Esq., Bath, had the best six varieties, these consisting of well-flowered specimens of Madame Lacharme, Edward Morren, John Hopper, Richard Wallace, Annie Wood, and Royal Standard. Mr. A. Hawkins, gardener to S. Jolley, Esq., was a good second. Mr. Cypher took the lead with nine show Pelargoniums. His examples of Miss Simpson, Madame Meschard, Triomphe de St. Mandé, Duchess of Edinburgh, Lady Isabel, Edward Perkins, C. Outram, and Empress of Russia being first-class in every respect. Mr. A. A. Walters and Mr. Tucker were the other prizewinners. Fancies and spotted sorts were well shown by Mr. H. F. Biggs, gardener to H. C. Hurle, Esq., and were awarded the first prize in both classes.

MISCELLANEOUS PLANT CLASSES.

Rhododendrons in pots were shown by several growers, but Messrs. G. Cooling & Son, Bath, easily secured the first position with remarkably well-flowered plants of Michael Waterer, Gulnare, Blandyanum, Christopher Snowdon, Mrs. Holford, Brayanum, and Lady Claremont, Messrs. H. C. Mayell and R. B. Cater were also successful with Rhododendrons, while the prizewinners in the classes for Cinerarias were Messrs. H. Gay, gardener to L. Daubeney, Esq.; W. Burridge, gardener to S. Butler, Esq.; and R. B. Cater, Esq.; and for Calceolarias, Messrs. Burridge and W. J. Mould, who took the prizes in the order named.

CUT FLOWERS.

Several excellent stands of cut Roses were shown, Messrs. Cooling and Son taking the first position with wonderfully fine blooms of Maréchal Niel, and very good blooms of Niphetos, Alba Rosea, Madame Willermoz, President, Hippolyte Jamain, Beauty of Waltham, and Mons. E. Y. Teas. R. B. Cater, Esq., was a very close second, his stand comprising fine blooms of La France, A. K. Williams, Catherine Mermet, Marie Van Houtte, Rubens, and Maréchal Niel. Mr. W. W. Kettlewell took the third prize, and others exhibited creditably. Tulips were well shown by Messrs. C. Cole, A. A. Tanner, and H. Hooper. Pansies by H. Hooper, W. Meddick, A. T. Hall, and F. Hooper, who took the prizes in the order named. The collections of twenty-four bunches of choice flowers were deservedly greatly admired, the winning stands comprising several good Orchids. Messrs. F. Perry, E. S. Cole, and W. J. Mould were the prizewinners. Hand bouquets were not extensively shown, but those staged by Messrs. S. Wakeham, gardener to J. W. Lovibond, Esq., T. Pearce, and E. S. Cole were highly creditable, the last named exhibitor being, however, rather hardly used. The epergne exhibited by Mr. H. S. James, gardener to A. Laverton, Esq., Farleigh Castle, was highly creditable, and for choiceness of flowers and taste in arrangement was deservedly awarded the first prize, Messrs. E. S. Cole and E. T. Hill also showed great taste, and were awarded the remaining prizes as named.

FRUIT AND VEGETABLES.

Mr. R. Miller, gardener to W. H. Long, Esq., Rood Ashton Park, Trowbridge, was the only exhibitor of a Pine Apple, and secured the first prize for a medium-sized fruit of Charlotte Rothschild. Mr. H. S. James had a similar award for a well-ripened fruit of Hero of Lockinge Melon. Mr. J. H. Vallance, gardener to J. C. Wall, Esq., Bristol, was the only exhibitor of Grapes, and was awarded the first prize for remarkably good and well-finished bunches of Black Hamburgh. Mr. Vallance also exhibited large well-ripened bunches of Foster's Seedling Grapes, and a good dish of Hathaway's Excelsior Tomatoes. Strawberries in pots were, on the whole, scarcely so good as usual, though no fault could be found with the examples of Oscar which gained Mr. J. Western, gardener to the Rev. C. C. Layard, the first prize. Mr. Jones was second with creditable pots of President. Mr. E. F. Collings had the best dish of Strawberries, variety Marguerite, and was followed by Messrs. Western and Jones. A dish of Uvedale's St. Germain Pear, staged by Mr. Burridge, gained the first prize; and in a larger class for Apples Mr. E. T. Hill was successful with Dutch Mignonne, Mr. J. Southard following with Newtown Pippin. Several fairly good collections of vegetables were shown, Mr. G. Garaway being successful with nine varieties, and was followed by Messrs. J. Western and Burridge. In the winning tray were good dishes of Mona's Pride Potatoes, Garaway's Late White Broccoli, American Red Top Turnips, Negro Long-pod Kidney Beans, and Wheeler's Improved Cabbage. Messrs. W. Smith, J. Horsell, and R. Fowler were successful with six dishes of vegetables; and Messrs. H. P. Westcott, H. Scott, E. Chedzey, W. Burridge, J. Curtis, G. Pymm, A. Hawkins were prizewinners in the various other classes for vegetables. The cottagers also staged a creditable lot of vegetables and common flowers.

Messrs. Cooling & Son, Bath, arranged groups of Clematises, Rhododendrons, Hybrid Perpetual Roses, miniature and single Roses, all extremely pretty, Pelargoniums and other plants, which added materially to the general effect. They also had a magnificent stand of Maréchal Niel Roses. Pansies were largely shown by Mr. Hooper; and Messrs. Cross and Steer sent cut blooms of a very fine nearly white Carnation named Louisa Ashburton.

ASPLENIUM HORRIDUM.

At the last meeting of the Royal Horticultural Society (May 13th), Mr. B. S. Williams, Upper Holloway, exhibited a plant of the distinct bold Fern *Asplenium horridum*, which was at once honoured with a first-class certificate. The species has long been known, having been described by Kaulfuss, and is included in Hooker's "Synopsis Filicum," but we believe it has not been previously introduced to cultivation, though Mr. Williams has had it for several years. In the plant shown the fronds were about 2 feet long, with pinnae 4 or 5 inches in length, but when mature they are frequently 3 feet long and 1 foot broad. Though these

are the extreme dimensions mentioned by Hooker, it is probable that under cultivation the fronds will become considerably larger, and the Fern will then have a majestic appearance like a dwarf Dicksonia. The fronds are dark green, rigid, and thick in substance, with a dark brown or black stipes and rachis, the lower portion being often clothed with rough brown scales, which impart a peculiar appearance to the plant, and to this is probably due its rather forbidding name.

The species is a native of the Sandwich Islands, being also found in Java, and is well represented in the woodcut (fig. 94), for which we are indebted to Mr. Williams.

BLUE FLOWERS.

HAVING seen the request of "Conservative Rose," on page 382 of the *Journal of Horticulture*, for the names of blue flowers, I have noted

cærulea, *Pleroma elegans*, *Psoralea pinnata*, *Tropæolum azureum*, and *Wissenia corymbosa*. This last is almost continually in flower.

This list might easily be greatly extended by including annuals and biennials, and also many rarer alpine plants. Those mentioned may however, be procured without difficulty.—G. GUTHRIE.

VINES BLEEDING.

WHEN we read week after week the different opinions of Vine-growers on the subject of Vines bleeding, it is a relief to see a sentence like that in the article by Mr. J. E. Waiting in your issue of May 1st, in which he makes the assertion that "Bleeding is a great injury to Vines, and water is the cause." Surely after that discussion ought to cease; but unfortunately there are a few who, like myself, do not rely sufficiently upon this statement to allow the matter to rest there, especially after the conflicting statements made in his article. Having seen as young Vines as those he mentions to which a liberal supply of water was given during

FIG. 94.—ASPLENIUM HORRIDUM.

the names of a few, mostly hardy perennials, and endeavoured to divide them as desired, only observing there must be of necessity a certain amount of overlapping, owing to difference of soil and situation, and also the somewhat erratic nature of our climate.

Spring.—*Anemone apennina* blanda, *Robinsoniana*, *Eritrichum nanum*, *Hepatica angulosa*, *triloba cærulea*, and *cærulea fl.-pl.*; *Muscari*, several species, and *Symphytum caucasicum*.

Summer.—*Aconitum pyramidale*, *Adenophora liliifolia suaveolens*, *Ajuga Brockbanki*, *Anchusa italica*, *Aphyllanthes monspeliensis*, *Borago laxiflora*, *Camassia esculenta*, *Campanula celtidifolia*, *garganica*, *persicifolia*; *Centaurea montana*, *Cichorium Intybus*, *Commelina cœlestis*, *Cyananthus lobatus*, *Cynoglossum montanum*, *Echinops Ritro*, *Eryngium amethystinum*, *Globularia trichosanthes*, *Linum perenne*, *Lithospermum prostratum*, *Pentstemon Jeffreyanum*, *Polemonium cæruleum* and *Richardsoni*, *Scabiosa caucasica* and *graminifolia*, *Sisyrinchium bermudianum*, *Trachelium cæruleum*, *Vinca herbacea*, *Viola pedata*, and *Wulfenia carinthiaca*.

Autumn.—*Aconitum autumnale*, *Campanula (Platycodon) autumnalis*, *Aster pilosa*, *pyrenaica*, *Shortii*.

Greenhouse.—*Agapanthus umbellatus*, *Agatheia cœlestis*, *Dianella*

winter and in the spring before starting, and no bleeding result, I come to the conclusion that though water indiscriminately given may be one of the causes of bleeding, yet it is not the sole cause.

Mr. Waiting says, "Old Vines, especially those planted inside, seldom receive half sufficient water neither summer nor winter, and this is the chief reason why Vines do not do well on the back walls of vieries." If this is the case, how does he reconcile it with the statement which he makes that water is the cause of bleeding? His statements amount to this—To grow Grapes successfully we must water heavily summer and winter, and if we do this the Vines will bleed; and, to follow his argument, if Vines bleed, they will suffer severely. But even on the point of Vines being injured by bleeding, I am not afraid to join issue with him. I have seen Vines bleed, though from other causes than overwatering, and I have also carefully watched them during the seasons following, and without exception I have found those that have bled do as well as those which did not bleed. In fact, I have now under my notice two Vines which have bled profusely in a house along with others which have not bled, and they are as healthy and are showing as good bunches as the others. Perhaps Mr. Waiting can tell us how it is that very often one or two Vines in a house bleed while all the others do not, though all receive the same supply of water.

But has he sufficient data for the assertion that an insufficient supply of water is the chief reason why Vines do not do well on back walls of vineries? I know some Vines treated liberally to water, and yet they fail to give a good crop. Might we not look for a more weighty reason in the fact that light is at least partially excluded by the front Vines? May I also ask your correspondent how he succeeded in getting Vines to bear, age, and to finish such a crop of Grapes so that from the roof to the floor the bunches were overlapping each other? My credulity is not sufficiently great to allow me to accept that statement without some proof. I should very much like to see those Vines, and should I ever visit Grange-over-Sands I shall make it a point, if Mr. Waiting does not object, to visit him.—JUSTITIA.

COBURGIA INCARNATA.

THIS member of the Amaryllis family I have recently grown, and found it to be a very handsome free-flowering plant. In general appearance it is much like the Imantophyllums, especially as regards the foliage, and if grown as a companion plant to that it cannot fail to prove acceptable, the spikes with their umbels of rich flesh-coloured flowers showing, as they do, to much advantage in a collection of plants. A point, too, in favour of them is their duration, each umbel of blooms keeping fresh and beautiful quite a month. We have thus had Coburgias in bloom since November, and our two last plants are now in full beauty. I have seen them described as half-hardy plants, and doubtless they are much more hardy than the Imantophyllums, but grown under similar conditions to the latter I have found them thrive well. A strong rich loam, with abundance of water during the growing period, and firm potting, are requisite. I find that by occasionally turning the plants round after the flower-spikes have attained their full height the beauty of the bloom is enhanced, as it causes them to fall gracefully and regularly round the top of the spike; otherwise the blooms are apt to all lean to one side. These plants are readily propagated by offsets, and grown as above will bloom the second season.—W. W. C.

NOTES FROM A SCOTTISH GARDEN.

THE BERMUDA LILY.—We have had some plants of this fine early-flowering Lily, the blossoms of which have lately unfolded their glistening petals. It is not well, perhaps, to estimate beauty by inches, but it is the only way by which some idea can be presented to the mind of those unacquainted with a flower like this, to give a statement of its size. The flowers are snowy white, with petals recurving and reflexed to the tubes, and measuring from tip to tip 7 inches across, the length of the tube being 6 inches. The perfume is rich and powerful. If such a plant does not become popular when once known, it must be because of some difficulty in its cultivation which has not as yet become apparent. I intend seeding the plants if possible and raising a stock of seedlings—a slow process, doubtless, but worth waiting for. The plants are amenable to forcing.

STAGE AURICULAS.—How handsome these are just now! I have a sufficient number of flowering plants to make quite a show in the greenhouse; and though they are not brilliant like Pelargoniums or Azaleas, but only sober little folks, with a good deal of "grey" in their composition, still they have an attractiveness about their puritanism, with such a pronounced perfume of Primrose banks floating over where they stand, that we cannot but love them. Gardeners seem to look at them askance and say, "Good enough for people who have nothing else to do but to potter about; such things are of no use in a big garden." Auriculas are quite as easy to manage as are Chrysanthemums, and there is less labour attached to their cultivation. If people place them in a hothouse from one end of the year to another, or consider they are doing their best for the plants if they repot them once in three years, perhaps relegating them to a corner of a cold frame, and there neglect the watering, it is not surprising if they fail.

I append the names of a few good sorts, mostly strong growers and showy. Self-edged varieties are most admired by beginners, but with experience the other sections become the more attractive. Of selfs the best are C. J. Perry, Lord of Lorne, Formosa, Eliza, Othello, Topsy, Pizarro, Mrs. Sturrock, and Blackbird. Of those with grey edges—Beauty, Robert Trail, George Lightbody (Headly), Atlas, Dr. Horner, Lancashire Hero, Alexander Meiklejohn, Richard Headly, and Confidence. Of white-edged sorts—Smiling Beauty, Aeme, Smith's Ne Plus Ultra, Glory, Mrs. Campbell, Sophia Dumaresque; and of sorts with green edges—Colonel Taylor, Imperator, Lovely Ann, Anna, Lyeurgus, and Admiral Napier.

REINE MARIE HENRIETTE ROSE.—This almost crimson Rose may now be looked upon as taking a high standard position. Maréchal Niel, Niphetos, then our subject, after that Gloire de Dijon and Cheshunt Hybrid when well established is the order in which I would place these. It is a free and strong grower, flowers to a bud, and produces beautifully green and well-

developed foliage. To those who have not as yet introduced this desirable kind into their gardens, no better advice could be offered than to procure it and plant at once.—X.

READING SHOW.

MAY 15TH.

WHEN the large tent in the Abbey Ruins at Reading is well filled there are few provincial shows which surpass this in beauty and effect. The terraced banks on each side permit of a very striking disposition of the exhibits, and under Mr. Phippen's able superintendence these are always displayed in the best possible manner. Unfortunately at the last autumn exhibition the competitors were not so numerous as might have been desired, and the show in consequence had a most unusual thin appearance. At the Exhibition held on Thursday last, however, ample compensation was made for past defects both in the number and quality of the exhibits. There was a due proportion of flowering and fine-foliage plants, though the groups arranged for effect were less numerous than usual, and rather less tasteful also; the competition in most of the leading classes was fairly good. The one great feature of the Show was the magnificent group of plants not for competition, contributed by Mr. Lees, which, being arranged upon the large semicircular mound at the end of the tent, had a most imposing effect, and attracted the admiration of all visitors.

Stove and Greenhouse Plants.—The principal class was that for twelve specimens, in which two well-known exhibitors entered—namely, Mr. James of Lower Norwood and Mr. Tudgey of Waltham Cross, but the first-named secured the premier award with comparative ease, for Mr. Tudgey's plants were not up to his usual high standard. On the other hand Mr. James's specimens were all good, healthy, and fresh, some being exceedingly meritorious. *Erica Cavendishiana*, for instance, 6 feet high and as much in diameter, well flowered, and thoroughly healthy, was a strong point in the collection. *Anthurium Andreanum*, too, was represented by what is probably the finest plant in the country, in splendid health and bearing fourteen of its large brilliantly coloured spathes. *Erica Lindleyana*, 6 feet high and 3 feet in diameter, very even, and profusely flowered, was also extremely attractive. Mr. Tudgey's best specimen was a gigantic *Erica Cavendishiana*, 6 feet high by 7 feet in diameter; *Clerodendron Balfourianum* and *Erica ventricosa* were good, but several other plants were weak. The best six specimens were from Mr. Mould, Pewsey, which were very neat and fresh, though not so large as the preceding. *Erica Cavendishiana*, 3 feet high; *Bougainvillea glabra*, slightly larger; *Pimelea Nieppergiana*, a very beautiful globular specimen 3 feet in diameter and profusely flowered; *Clerodendron Balfourianum*, *Pimelea Hendersoni*, and *Azalea Sir Charles Napier* were also well flowered. Mr. Mortimer, gardener to Major Storer, Purley Park, followed very closely, his plants including a handsome example of *Tabernaemontana coronaria* 5 feet across, but though in the best possible condition as regards health, the flowers were not quite expanded, and a week later the plant would have been much more effective. *Bougainvillea glabra*, *Rhynchospermum jasminoides*, and *Medinilla magnifica* 6 feet high, were the best of the other plants. Two collections of four specimens were staged. Mr. Baskett, gardener to W. J. Palmer, Esq., Reading, won chief honours with neat examples of *Anthurium Andreanum*, *Vinca alba*, a *Clerodendron*, and *Bougainvillea*. Mr. Armitage, gardener to W. Clarke, Esq., Reading, took the second place, showing *Begonia Snowflake*, *Chrysanthemum frutescens*, and *Chorozema Chandleri*, very neat and fresh. For a single specimen Mr. Mould was first with *Boronia pinnata*, globular, 4 feet in diameter, well flowered, and extremely healthy. Mr. James followed very closely with *Erica depressa* 4 feet high, fresh and well flowered.

Ferns.—Several particularly fine collections of these were shown, and rarely have Ferns been better represented at Reading than on this occasion. Mr. Mortimer's premier exhibit of fifteen specimens was especially praiseworthy, the plants being all distinguished by a remarkable vigour that indicated the most careful culture. *Adiantums* were particularly fine, *A. gracillimum*, *A. cuneatum*, *A. concinnum latum*, and *A. formosum* being the largest and best. *Gymnogramma peruviana argyrophylla* was grandly shown; other noteworthy plants being *Selaginella Galeottii*, *Platynerium alecorne*, and *Lycopodium squarrosum*. Mr. Mayne, gardener to Miss Moon, Reading, followed with much smaller plants, mostly in baskets, but very pretty. By far the largest plants were those staged in the class for six Ferns, in which Mr. Mortimer was again the most successful exhibitor, securing the chief position with exceedingly handsome specimens, including *Davallia Mooreana* 6 feet across, *Alsophila australis* 7 feet high, *Adiantum eultratum* as much in diameter, *Dicksonia antaretica* nearly 8 feet high, *Adiantum eardiochlena* 7 feet across, and *Davallia bullata* 5 feet in diameter, extremely fresh and beautiful. This collection was one of the most meritorious in the whole Exhibition, considering the excellent condition of the plants, every one of which was fresh healthy. Mr. Mould took the second place, also with well-grown plants, his *Gleichenias Mendelli* and *rupestris* being in most praiseworthy condition. Mr. James secured the third position, and his Ferns, like those in the two preceding collections, deserved high commendation for their freshness. These three exhibits contributed greatly to the beauty of the Show. In a smaller class Mr. Armitage was the chief prizetaker.

Fine-foliage Plants.—Though less numerous than the Ferns, these held almost as imposing a position in the tent, owing to the great size of the plants entered. Mr. Mortimer, who was very successful in all the principal classes, was again first with six fine-foliage plants, staging admirable specimens of *Pandanus Veitchi*, *Croton majesticus*, and *C. Weismanni* beautifully coloured, *Alocasia Thibautiana* and *A. metallica* very handsome, and *Yucca aloifolia variegata*. Mr. Tudgey's plants, which were placed second, were considerably larger, especially his well-known *Pritchardia pacifica*, which is upwards of 12 feet high. Two Cycads were also of great size, but they were not so fresh and even as in the winning group. Mr. James was third, his most notable plants being a very large *Pandanus Veitchi* and *Theophrasta imperialis*.

Orchids.—Only two classes are provided for these—namely, one for three plants, and the other for a single specimen, but in both some excellent examples were staged. Mr. James won the first place with an admirably grown plant of *Odontoglossum vexillarium* bearing about forty flowers, *Lælia purpurata* with sixteen large and richly coloured flowers, and *Dendro-*

bium nobile profusely flowered. Mr. Mortimer took the second place, *Dendrobium thysiflorum* having seven spikes, *Vanda suavis* two spikes of twelve flowers each, and *Dendrobium densiflorum* with forty-five spikes, a remarkable specimen, which nearly gained the first prize for the collection. Mr. Baskett was third, his plants being *Cypripedium caudatum*, *Cattleya Mossiæ* with nine flowers, and *Dendrobium thysiflorum* with seven spikes. The same exhibitor was first with a single specimen *Cymbidium Lowianum*, having two spikes of sixteen flowers each. Mr. James was second, showing *Cattleya Mendelli* bearing thirteen flowers.

Groups.—In the class for a group of plants arranged for effect in a space of 12 feet by 10 feet, Mr. Phippen, Reading, won the leading prize, but the arrangement was not quite so effective as that usually distinguishing his contributions. The groundwork consisted of miscellaneous plants, such as *Spiræas*, *Pelargoniums*, *Coleuses*, with taller plants of *Campanulas*, *Lilies*, *Chrysanthemum frutescens* *Etoile d'Or*, and a back of *Palms* and *Pandanus*, the margin comprising *Isolepis* and *Selaginellas* alternately. Mr. James was placed second, but the group scarcely merited a place, for it was extremely thin and dull, though including several good Orchids. The competition was keener in the class for a group 6 feet by 4 feet, but even in that there was a falling-off in artisticness. Mr. Woolford, gardener to H. Palmer, Esq., was adjudged first honours for a bright collection of *Calceolarias*, *Gloxinias*, *Ericas*, *Rhododendrons*, *Richardias*, *Lilies*, and *Lobelias*, with a due proportion of Ferns. Mr. Hatch, gardener to S. B. Stevens, Esq., Reading, followed, *Roses*, *Begonias*, *Coleuses*, *Pelargoniums*, and *Nephrolepis* forming the chief features. Mr. Sumner, gardener to J. H. Millard, Esq., Reading, was a good third, having a graceful and pretty group, in which *Fuchsias*, *Pelargoniums*, and *Azaleas* chiefly predominated. Extra prizes were awarded to Mr. Balchin, gardener to B. Simonds, Esq.; Mr. House, gardener to J. O. Taylor, Esq., and Mr. Mayne in this class, all the groups being bright. A magnificent bank of *Rhododendrons* from Mr. Ashby, gardener to W. Fanning, Esq., gained him the first prize in the class for those plants, but it is to be regretted that only one collection was staged, as the effect of the show would have been much improved had there been two or three competitors.

Azaleas.—Several collections of remarkably well-flowered specimens were staged in the classes for *Azaleas*, especially noteworthy being those from Mr. Lockie, Oakley Park Gardens, Windsor, in the class for six plants in 8-inch pots. These were beautifully even examples, and deservedly secured Mr. Lockie the first prize. They were about 2 feet high, and covered with large bright flowers, the best being *Model*, *Lady Scott*, *Warrior*, *Eclatante*, and *Mdlle. Verschaffelt*. Mr. Armitage and Mr. Baskett were respectively second and third with less profusely flowered plants. Mr. Lockie was again the premier exhibitor of four *Azaleas*, showing perfect little globes of flowers, extremely handsome; *Reine des Pays Bas*, *Roi d'Holland*, and *Duchesse Adelaide de Nassau* were the best. Mr. Mortimer was a close second with neat plants.

Pelargoniums are generally in strong force at Reading, and, though not quite so numerous as usual, some creditable plants were staged. Mr. Ashby had the best nine specimens of show varieties, each about 3 feet in diameter and flowering profusely. *Ruth*, *Empress*, *Triomphe de St. Mandé*, *Claribel*, *Crimson King*, and *Duchess of Edinburgh* were the principal varieties, the last bearing a great number of fine flowers. In other classes Mr. Mortimer and Mr. Powell, gardener to G. Gilligan, Esq., Reading, were the prizetakers. Mr. Mould was the only exhibitor of six *Ericas*, taking the first position with admirably neat and well-flowered specimens. The same exhibitor was first with six *Roses* in pots, Mr. Tranter of Upper Assenden also scoring a success with *Roses* in another class. Mr. Baskett took the lead with six *Gloxinias* in 32 and 24-size pots, with about two dozen blooms each, fine in substance and colours. Mr. Farey, gardener to O. Stephens, Esq., Woodley Hill, and Mr. Mortimer were the other prizetakers, the last having a handsome plant of *Boule de Neige* with about thirty flowers. Bright and beautiful plants of *Calceolarias* were contributed by Messrs. Baskett, Lockie, and Hatch. Table plants were represented by some very creditable specimens; those from Mr. Ross, Welford Park Gardens, Newbury, for which the first prize was awarded, were very neat and well grown, the soil being surfaced with *Selaginella*. *Pandanus Veitchi*, *Yucca variegata*, *Croton Eyresi*, *Caladium argyrites*, and a pretty narrow-leaved seedling *Croton* being the best. Mr. Baskett, who followed, had larger plants. *Fuchsias* were not of remarkable beauty, but were fairly well flowered. Messrs. Sumner, Mortimer, and Mayne were the prizetakers.

Cut flowers were numerous and well shown. The best general collections of stove and greenhouse were from Messrs. Ross, Mortimer, Woolford, James, and Phippen, all including good examples of the most useful and attractive of indoor plants. *Rose* blooms were well represented by Messrs. Gurden, Tranter, and Elliott. *Pansies* were chiefly shown by Mr. Bridge, gardener to J. F. Hall, Esq., Erleigh Court; Mr. Lawrence, gardener to Mrs. Owen Knox, Carshalton; and Mr. Shrimpton. Table decorations, bouquets, and button-holes were contributed by several exhibitors, the leading prizes being secured by Mr. Phippen.

Fruit.—The display in the classes for fruit was rather small. For two bunches of black Grapes Mr. Howe, gardener to Sir R. Sutton, Benham Park, was first with Black *Hamburgh* well coloured, the bunches and berries of good size for such early fruit. Mr. Ashby and Mr. Baskett followed with the same variety. In the white Grape class Mr. Ashby took the first prize with fairly good *Foster's Seedling*, Mr. Baskett being second with the same variety, but rather green. Mr. Howe had the best dish of *Figs White Marseilles*, and Mr. Mortimer contributed the best dish of *Strawberries* Sir Joseph Paxton, fine, even, and beautifully ripened.

Vegetables.—Three creditable collections of vegetables were entered, Mr. Lockie gaining the premier award with most praiseworthy examples of *Lyon Leeks*, *Royal Windsor Cucumbers*, *American Wonder Peas*, *Sutton's Reading Perfection Tomatoes*, *Royal Ashleaf Potatoes*, *Mammoth Negro Beans*, *French Horn Carrots*, *Queen Onions*, *Late Queen Broccoli*, *Asparagus*, *Cabbage*, &c. Mr. Howe, who was placed second, also had a good collection, his *Ne Plus Ultra Cucumbers*, *Tomatoes*, and *Asparagus* being particularly fine. Mr. Read, gardener to J. Wilder Esq., Purley Hall, followed with a good representative collection. In other classes for *Potatoes*, *Peas*, *Beans*, *Asparagus*, *Broccoli*, and *Rhubarb*, Messrs. Read, Elliott, Lockie, Clark,

Balchin, and Lipscombe were the prizetakers. Messrs. Sutton & Sons' prizes for *Cucumbers* and *Potatoes* brought a number of competitors, all staging good examples. For a brace of *Cucumbers* Mr. Mortimer was first with *Purley Park Hero*, very even and handsome. Mr. Howe and Mr. House followed closely. For a dish of kidney *Potatoes* Mr. Lockie was first with *Sutton's Early Ashleaf* and second with *Sutton's Ringleader*. For round *Potatoes* Mr. Howe led with *Early Market*, and Mr. Lockie second with *First and Best*.

Miscellaneous.—By far the most important of the non-competing exhibits was the group of plants from Mr. Lees, gardener to Mrs. Marsland, The Wilderness, Reading. This consisted of a groundwork of Ferns, *Azaleas*, *Begonias*, *Auriculas*, *Selaginellas*, and *Panicum variegatum*, with taller *Palms*, Ferns, and *Fuchsias*, to impart a diversity to the display. Mr. C. Turner, Slough, exhibited collections of *Pelargoniums*, *Carnations*, *Roses*, and *Alpine Auriculas*, including a large number of fine varieties, several of which were certificated. Mr. J. Fyfe had a box of twelve good *Auriculas*. Boxes of handsome *Maréchal Niel* *Rose* blooms were shown by Mr. Tranter, and *Clematises* by Mr. Bridge. For most of the above extra prizes were awarded, and certificates were adjudged for the following plants, a certificate of merit being awarded to the Chadborn & Coldwell Company, Upper Thames Street, London, for their *Excelsior* lawn mower.

To Mr. Turner for *Carnations* *Mrs. Maclaren*, crimson bizarre, previously certificated at Kensington; *Hector*, bright scarlet self, fine colour, and well-formed substantial flower; *Rufus*, deep scarlet self, very rich and effective; *Ruby*, purple self, a beautiful soft tint; and *Mrs. Llewelyn*, a rosy pink self, large full handsome bloom.

Alpine Auriculas *Mrs. Ball*, rich crimson shaded, pale tube, bold handsome flower, very free; *Homer*, deep red shaded, bright gold tube, distinct; and *Eclipse*, crimson purple shaded, gold tube, rich and effective.

SYRINGING VINES.

I FIND one of your readers has been trying Hudson's dry soap in water to syringe his Vines, and is very much alarmed what the result will be. To attempt to syringe Vines in flower to clear off the blossom and pollen is bad enough, but using soapy water when the berries are not thinned, with great fire heat and a treacherous sun shining, rust is sure to follow, as the whole mass gets baked on the berries, and once done no after syringing will remove it. Clear water would do the same. I shall be very sorry if any harm occurs from this misapplication. Never syringe the bunches from the time of coming into flower until they are thinned, a few days later is better.—J. E. WAITING, *Grange-over-Sands*.

ROYAL BOTANIC SOCIETY.

MAY 21ST.

BEAUTIFUL as the summer Exhibitions of the Royal Botanic Society invariably are, that held on Wednesday last was, in the opinion of many, the finest they have ever had thus early in the season. From whatever point the Exhibition was viewed, the effect was grand in the extreme. Glowing masses of colour were furnished by the profusely flowered specimen *Azaleas*; rich and soft shades of blue, purple, and mauve by the unrivalled *Clematises*; rich green foliage by Ferns and *Palms*, and exquisite indescribable tints by the extraordinary collections of Orchids. The nurserymen's groups also, which occupied the central banks, were unusually elegant, and the whole arrangement of the Show indicated the most careful and tasteful superintendence. Mr. Coomber, indeed, deserves the greatest praise for the admirable and effective manner in which the several classes were disposed and the colours contrasted, blended, or softened. Extremely favourable weather induced the attendance of a large company of distinguished visitors, and the general impression was that the Exhibition was one of the greatest successes hitherto scored by the Society.

ORCHIDS.—A superb display of Orchids was provided, no less than six handsome collections being entered in the amateurs' class, forming a bank of unequalled beauty. The *Dorchester* plants were magnificent, the grand plant of *Cattleya Skinneri* being awarded the *Veitch Memorial* medal in the class for the best Orchid in the Show. It was about 4 feet in diameter, with twenty-four trusses of six to eight flowers each of the most lovely soft rosy crimson imaginable. *Thunia Marshalli*, *Dendrobium nobile*, *Masdevallia Harryana splendens*, *Dendrobium pulchellum*, and *D. Falconeri* were similarly noteworthy. The *Sydenham* plants were profusely flowered; *Dendrobium thysiflorum* with seven spikes, *Cymbidium Lowianum* with four grand spikes, *Masdevallia Harryana*, fine colour; *Oncidium Marshallianum*, with a magnificent panicle; *Cypripedium caudatum*, with twenty flowers, and others similarly good. The most effective plant in the Bickley collection was *Sobralia macrantha*, with two dozen handsome flowers. In addition to the prizetakers a large silver medal was awarded to Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, for some handsome specimens; a silver medal was also adjudged to Mr. J. Douglas, gardener to F. Whitbourne, Esq., Great Gearies; and a large bronze medal to Mr. J. Child, gardener to W. J. Bell, Esq., Garbrand Hall, Ewell, for exhibits in the same class. Only three collections were entered in the nurserymen's class, and the plants generally were not so large or remarkable as in the amateurs' section. Mr. James, however, had some

handsome Cattleyas and a deep-coloured *Odontoglossum vexillarium*. The prizes were awarded as follows:—Twelve Orchids (amateurs) first Mr. Powell, gardener to W. E. Brymer, Esq., M.P., Ilslington House, Dorchester; second Mr. Catt, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham; third Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., Oldfield, Bickley. Nurserymen: first Mr. James, Upper Norwood; second Mr. Cypher, Cheltenham; third Messrs. Jackson & Son, Kingston.

AZALEAS.—The exhibits in these classes furnished a most welcome display of colour. Rarely are they seen in finer condition. The Slough plants were particularly fresh and beautiful, neat pyramids of Cordon Bleu, Mrs. Turner, Apollo, and Reine des Fleurs being especially notable; while in the larger specimens *Comtesse de Flandres* 6 feet high and across, *Duc de Nassau* and *Chelsoni*, similar, were grand. Mr. Child's plants were grandly flowered, *A. concinnum* Magnet and Model being so densely covered with blooms that the foliage was scarcely visible. The prizetakers were—twelve Azaleas (open) first Mr. C. Turner; second Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate; third Mr. James. Six Azaleas in 12-inch pots (amateurs) first Mr. J. Child, gardener to W. J. Bell, Esq., Garbrand Hall, Ewell; second Mr. J. Wheeler, gardener to Lady Goldsmid, St. John's Lodge, Regent's Park; third Mr. Eason. Six Azaleas (nurserymen) first Mr. C. Turner, second Mr. Cypher. Six Azaleas (amateurs) first Mr. Child, third Mr. Wheeler.

STOVE AND GREENHOUSE PLANTS.—The majority of the plants shown in these collections were in fresh and excellent condition, but Mr. Chapman's plants deserve especial praise for their vigour. *Ixora coccinea*, *Erica affinis*, *Aphelaxis grandiflora*, and *Anthurium Schertzerianum* with nearly one hundred spathes were remarkably fine. *Acrophyllum venosum* and *Erica Cavendishiana* were also finely shown in the smaller class. Mr. Chapman also secured the Veitch Memorial medal for the best stove or greenhouse plant in flower—namely, a specimen of *Hedera tulipifera* about 6 feet high and rather more in diameter, globular, even, and covered with large flowers. Mr. Cypher's specimens were also handsome, though some were scarcely in the best condition. *Erica depressa* 5 feet high and as much in diameter was greatly admired. The prizes were awarded as follows:—Twelve specimens (nurserymen) first Mr. J. Cypher, Cheltenham; second Mr. H. James, Lower Norwood; third Messrs. Jackson & Son, Kingston. Ten specimens (amateurs) first Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley; second Mr. C. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley; third Mr. Child. Six specimens (amateurs) first Mr. Chapman, third Mr. Wheeler. Six specimens (nurserymen) first Mr. Cypher, second Mr. Mould, third Mr. E. Tudgey.

ROSES.—The Cheshunt giants and the Slough smaller but beautiful specimens formed the most interesting portion of the display in these classes, and all were equally fine in general condition. Of the former Charles Lawson, Anna Alexieff, and Edouard Morren were the most noteworthy, with superb blooms. Mr. Turner's best were *La France*, *Mad. de St. Joseph* and *Thérèse Levet*. The prizetakers were—Nine Roses (nurserymen) first Messrs. Paul & Son, Cheshunt; third Mr. J. Mould, Pewsey, Wilts. Six Roses (amateurs) first Mr. Wiggins, gardener to W. Clay, Esq., Kingston; second Mr. Tranter, Upper Assenden. Twenty Roses (nurserymen) first Mr. C. Turner; second Messrs. Paul & Son.

PELARGONIUMS.—The competition was good in these classes, and formed a beautiful bank in the corridor near the Rhododendron tent. Mr. Turner's plants were as usual in splendid condition, both Show and Fancy varieties being superbly flowered. Mr. Hill's collection of Show varieties also included some admirably grown plants with large trusses; and his Fancy varieties were equally praiseworthy. The prizetakers were—six plants (amateurs), first Mr. Hill, gardener to H. Little, Esq., Hillingdon Place, Uxbridge; second Mr. Wiggins; third Mr. W. Griffin, Gothic Lodge, Sydenham. Nurserymen: first Mr. C. Turner, second Mr. J. Cypher; third Mr. J. Odell, Shepherd's Bush. Six Fancy varieties (open): first Mr. C. Turner, second Mr. Hill, third Mr. Wiggins.

CLEMATISES.—Messrs. Jackman & Son, Woking, were the only exhibitors in the class for twelve plants, and deservedly secured premier honours for grand globular specimens 5 or 6 feet high, and bearing abundance of handsome blooms. All the varieties were good, but the following deserve especial mention:—*Princess of Wales*, purple mauve, very large; *Madame Van Houtte*, creamy white; *Impératrice Eugénie*, white; *Duchess of Edinburgh*, double, white; *Fairy Queen*, bluish white, striped with rose; and *Lady Caroline Nevill*, delicate mauve, with darker stripes.

FINE-FOLIAGE PLANTS.—The magnificent plants from Crawley were the feature in this class, the gigantic *Areca sapida*, *Latania borbonica*, and *Cycas revoluta* forming the strong points. Mr. Wheeler's plants were chiefly Palms, massive and healthy. The prizetakers for six were (amateurs)—first Mr. C. Rann, second Mr. Wheeler. Nurserymen: first Mr. Cypher, second Mr. James, third Mr. Tudgey.

Three very creditable collections of Heaths were staged, all very healthy, and several exceedingly well flowered. Mr. Tudgey's specimens were in admirable condition, especially *E. coccinea* minor. Messrs. Jackson's best plant was *Erica ventricosa coccinea*, 4 feet across, and a mass of flowers. The prizetakers were for six (open), first Mr. Tudgey, second Messrs. Jackson and Son; third Mr. Cypher.

The entries in the class for six Ferns were comparatively few, and by far the best were those from Mr. Douglas, chiefly *Dicksonias* and *Adiantums* in most vigorous health. First Mr. J. Douglas; second Mr. Wheeler; third Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's Lodge, Regent's Park.

The prizes for Gloxinias were secured by Mr. H. Eason and Mr. C. Rann, both showing fairly good specimens, and Mr. J. Douglas was the only exhibitor of alpine plants, gaining the premier prize for a pretty collection.

GROUPS.—These contributed greatly to the beauty of the Exhibition, the four central groups being uncommonly handsome. A silver-gilt medal was awarded to Mr. B. S. Williams, Upper Holloway, for an extensive collection of choice Orchids, tastefully arranged with Ferns and Palms. Large numbers of species and varieties were represented, the principal of which are enumerated on another page. A silver medal was awarded to Messrs. J. Laing

and Co., Forest Hill, for an imposing group of fine-foliage plants, *Dracenas*, Palms, Crotons, and *Caladiums*, with a margin of choice new tuberous *Begonias*, *Gloxinias*, and Ferns. Messrs. E. G. Henderson & Son, Maida Vale, were awarded a small silver medal for a group of miscellaneous stove and greenhouse plants, *Blandfordias* being largely represented. A similar award was also granted to Messrs. J. Cutbush & Son, Highgate, for a bright and tasteful group of Azaleas and miscellaneous greenhouse plants very freely flowered.

One of the most remarkable groups in the Exhibition was a collection of Crotons from Messrs. R. P. Ker & Son, Aigburth, Liverpool, for which a silver medal was awarded. They included a great number of new and grandly coloured varieties, and the group was much admired by all the visitors, as it produced a fine bank of colour. A bronze medal was awarded to Mr. Archer, The Grange, Highbury, for a group of fine-foliage plants, and to Mr. Mould for a similar group. A silver medal was awarded to Messrs. W. Paul & Son, Waltham Cross, for twenty boxes of Rose blooms, representing a great number of varieties in first-rate condition. A bronze medal was awarded to Messrs. J. Carter & Co., Holborn, for a group of richly coloured *Calceolarias*, compact in habit and bearing large blooms. A small silver medal was adjudged to Messrs. F. Sander & Co., St. Albans, for a group of *Odontoglossum Alexandrae* and Ferns. A bronze medal was awarded to Captain Halford Thompson, Claremont, Exeter, for baskets of plants grown in moss. The New Plant and Bulb Company, Colchester, showed a collection of Japanese Maples. A bronze medal was awarded to Messrs. Barr & Son, Covent Garden, for a choice group of hardy flowers. Mr. H. Hooper, Bath, exhibited boxes of Pansy blooms; Messrs. Cross & Steer, Salisbury, had specimens of their new perpetual *Carnation Louisa Ashburton*, fringed white, with slight pink tinge.

New plants were very numerous, and first-class certificates were awarded for the following:—To Messrs. Laing & Co. for tuberous *Begonias* General Gordon, Distinction, Earl of Chesterfield, T. Hewitt, Lady Chesterfield, Mr. A. Forbes, Mrs. Weekes; *Caladiums*—*Madame Mitzana*, Baron James de Rothschild, and *L'Aurore*; *Gloxinias*—Mrs. Coomber, Beauty, and George Amer. To Messrs. W. Paul & Son for Tea Rose *Etendard de Jeanne d'Arc*. To Mr. James for *Odontoglossum polyxanthum* and *Odontoglossum mulus*. To Mr. Cypher for *Cypripedium Röbelinii*. To the New Plant and Bulb Company for *Acer palmatum roseum* and *A. palmatum aureum*. To Messrs. Sanders & Co. for *Odontoglossum elegans superbissimum*. To Messrs. R. P. Ker & Son for *Ficus elastica variegata*, and Crotons *Flambeau*, *Sunrise*, and *mosaicus*. To Mr. Little for *Pelargoniums* G. Shepherd and Harvester; and to Mr. B. S. Williams for *Cypripedium ciliolare*.

KITCHEN GARDEN.

WHERE all previous directions have been carried out as regards sowing and planting work in this department will now be less pressing than it was some time ago. Most of our hands are now "bedding out" the flower garden or dressing the pleasure grounds; but still there are many little details requiring attention in the vegetable garden which should on no account be neglected, as, although omissions may not be felt just now, they will be by the time the produce is required.

Late Peas.—A large sowing of these should be made for fruiting in September and October. Sutton's Latest of All is the best late Pea we have grown; then comes Laxton's Omega. They are both comparatively dwarf, not growing more than 4 feet high, very prolific, and first-rate in quality. Ne Plus Ultra is much taller, and not so convenient for the majority of gardens. The soil should be deep and rich, the position a sunny one, and as much as possible away from draughts and the haunts of birds. The rows may either be sown in one quarter or in any convenient place throughout the garden. They should never be so close as to crowd each other or obstruct the sun's rays. Stake successional crops of Peas, and as soon as the pods have been gathered from the earliest rows clear the old haulm off at once and fill up the ground with late Cauliflowers.

Tomatoes.—Plants of these which have been grown on and hardened with the object of planting them out should now be placed in their fruiting quarters. The best of all places for them is a sunny south wall. We never grow ours on a wall by themselves, but plant them between the wall trees wherever there is a vacant space. Avoid giving them a rich mixture. Put nothing but loam under the roots; then they will make little or no superfluous wood, bear abundance of fruits, which can easily be assisted with liquid manure. Make the soil very firm about the roots and nail the stem to the wall. Tomato fruits are now plentiful under glass, and the earliest fruiting plants are being much benefited by liberal supplies of liquid manure.

Turnips.—Sow a good breadth of Veitch's Red Globe to come in through August and September. Thin advancing crops; any early quarters which may "bolt," as they are most liable to do, should be cleared off at once, and sow again.

Radish seed should now be sown every fortnight. Small and frequent sowings are the only ones which will give a supply of really tender roots. Early crops are now too large for use, and what remains of them should be thrown away.

Lettuce seed may be sown, as it is from those put in now we have our

supplies during August and September. Tom Thumb or Tennis Ball is a choice summer Lettuce, and the Kingsholm Cos variety is useful in warm weather, being very large, tender, and crisp.

Kidney Beans.—A good sowing of the Canadian Wonder variety should be put into good soil and a favoured position. This is the finest of all the dwarf Beans, and should be grown in every garden. It grows 18 inches high and is rather spreading, and for this reason the seed should be planted singly 6 or 8 inches apart.

Rhubarb and Seakale showing bloom should have all the flower stems cut off to the ground. Asparagus should have a handful of salt put round each crown when it is raining.

Spinach.—The supply of this can only be kept up by frequent sowings at this season. We sow a few rows weekly. The first sowing which has done us good service is now over, and has been thrown away. Lettuces have been dibbled in its place.

Earth up Cauliflowers, Cabbages, early Brussels Sprouts &c., before the plants become top-heavy. Hoe between all growing crops. Do not let weeds gain any size, and on no account allow them to seed.

FRUIT FORCING.

VINES.—*Early Houses*.—Vines that have been cleared of fruit should have a good washing with the syringe or engine, and this should be repeated occasionally, as it is important that the foliage be kept in good condition for as long as possible. Enough water or tepid liquid manure should be given to maintain a moist condition of the soil, and to prevent early resting encourage a moderate extension of the laterals, with a temperature of 60°, ventilating freely on all favourable occasions. Houses in which the Grapes are ripe may be damped occasionally, as a moderate amount of atmospheric moisture will not interfere with the keeping of the Grapes, providing the air is not close; and with a temperature of 60° their requirements will be met as regards heat at night, and a few degrees higher in the daytime. When the sun is powerful it will be advisable to employ a light shading, or Hamburgs will lose colour and flavour.

Houses of Vines with the Grapes Swelling.—To assist the fruit in swelling allow as much lateral extension as can be done without crowding the space with more foliage than can have exposure to light and air, which will maintain activity at the roots and cause nutriment to be taken up freely. Mulch the surface with short manure, which should be well watered, it not being possible to over-water Vines in a healthy state when swelling-off their crops, provided the border is efficiently drained. Ventilate early in the day, increasing it with the sun heat, and keep through the day at 80° to 85°, closing at 80°, when the floors, borders, &c., should be damped so as to secure a genial condition of the atmosphere; and before nightfall sprinkle the floors with guano water or liquid manure, the ammonia from which is highly beneficial to the Vines, and the liability to attacks of red spider is considerably reduced. Artificial heat will only be necessary to prevent the temperature falling below 60° at night, and to insure 70° to 75° in the daytime in dull weather, making up for lost time when the sun shines. Outside borders that lie high and dry must be watered thoroughly in dry weather, having the surface mulched with short manure. Vines bearing Grapes that are beginning to colour require a thorough soaking of liquid manure in a tepid state both to inside and outside border, and mulch if necessary. Continue a good atmospheric moisture, as the Grapes swell considerably in ripening, and ventilate a little constantly. Close early with plenty of sun heat, and maintain moderate heat in the pipes so as to allow a circulation of warm air. If the Vines are carrying heavy crops keep the house rather cool at night, so as to rest the Vines, and thus given a little more time they will be able to finish off the crop satisfactorily, whereas if pushed they would in all probability colour very indifferently. The laterals may be allowed to extend, especially if the crop be heavy and there is space for their exposure to light.

In succession houses keep the stopping and tying regularly performed. Thin Hamburgs as soon as set, and other Grapes as soon as it is seen which to remove by the properly fertilised berries taking the lead.

Early Autumn and Late Houses.—Daily attention will be needed in stopping and tying, laying in laterals as long as there is space for the full development of foliage without crowding. Thin the berries freely, and endeavour to obtain handsome medium-sized bunches in preference to large and loose ones that seldom finish satisfactorily. The Vines from which the latest Black Hamburg Grapes are obtained are now in flower, and will only need artificial aid so as to prevent the temperature falling below 55° at night and to secure 65° in the daytime, a high artificial temperature at this season being apt to draw out the bunches, and Hamburgs with long weak footstalks to the berries do not keep well, besides rendering them loose in appearance. The late varieties are now in flower, and as many of these do not set well pollen should be taken from Hamburgs and applied to the shy setters. As a rule, the thin-skinned Grapes do not need so high a temperature as Muscats, for, although they do well enough under similar conditions of heat in the early stages of growth, but when ripening the heat required for finishing Muscats does not favour the colouring of the black varieties, as they require more time for making and maturing their growth; hence to grow the finer late black Grapes they should have a house to themselves. Houses in which Grapes are stoning must be kept cool and regular in temperature at night, as the Vines in the best of condition must have time, and the roots cannot do more than the process demands, which is certainly an exhaustive one, it being better to allow the supply of nutriment to exceed the demand than want more than they receive, which is only too often apparent in the total cessation of lateral growth during the stoning process. The thinning of

the main crop of Muscats will be completed, and the borders need mulching with good decayed manure, and copious supplies of tepid liquid manure or water are necessary. The outside borders should also be mulched, and in dry weather be given copious supplies of water or liquid manure as may be needed.

Early pot Vines intended for fruiting next spring should be given more air, and the foliage syringed so as to keep it free from red spider, as upon this and a thoroughly solidified and matured growth depends the future success, and this can only be effected by the preservation in health of the main leaves. Feed liberally, so as to secure a well-developed growth.

MELONS.—Plants in flower must have plenty of air in the daytime, not syringing until they have set their fruit, after which it can be brought into use again. Fertilise the flowers daily until a sufficient number on a plant are set, and stop one joint beyond the fruit. When a sufficient number of fruits are set and swelling earth up the plants, giving some good rich rather strong loam, and firm it well, having previously had it in the house to become warmed, and before earthing supply tepid water liberally. Four to six fruits will be sufficient to leave on a plant, apportioning them according to the size of the kind and the individual strength of the plants. Plants swelling their crops should have free supplies of tepid liquid manure, and a moist genial condition of the atmosphere secured by syringing in the early part of the afternoon or at closing time, and damp the house two or three times a day, or whenever the floors become dry. Keep the laterals regularly stopped, and if likely to become crowded thin them out gradually, so as not to give a check to the roots. Close as soon as safe in the afternoon, or from 3 to 4 p.m., and if the temperature rise to 90° afterwards it will be an advantage, keeping through the day at 80° to 85° or 90°, admitting a little air early at 75° to 80°, and increasing it with the heat, not lower, but to keep it from becoming too high. Afford support to the fruit in good time. When the fruit gives indications of ripening cease syringing, but maintain a genial condition of the atmosphere by damping available surfaces occasionally, giving air freely, and maintaining a circulation of warm air constantly, lessening the supply of water to the roots.

Continue the earthing-up of the hillocks in pits and frames as the roots protrude through the sides of the mound, repeating until the allotted space for that purpose is filled. See that the plants do not suffer for want of water, and do not give it so frequently as to sodden the soil—once or twice a week according to the weather will be sufficiently often; and in watering keep it from the collar of the plants so as to avoid canker. If this appear rub quicklime into the affected parts. The shoots of young plants which are now covering the surface of the beds should be thinned out to about four, taking two to the front and the other to the back, and taking out their points when a foot from the sides of the frame or pit. This will result in side or fruit-bearing shoots, and when the flowers on these expand impregnate when the pollen is dry, stopping one joint beyond the fruit. Three or four fruits to a plant are ample according to its strength, and when these are secured remove all the other flowers, male and female, and encourage the swelling by closing early, or from 3.30 to 4 p.m., syringing or sprinkling overhead at the same time. If the temperature does not rise above 90° or 95° no harm will result, but if it do admit a little air for a short time, finally closing at 85°. Keep the laterals closely pinched or thinned as may be necessary, it being important that the foliage be not too crowded and that the main foliage be kept in good condition.

PLANT HOUSES.

Cyclamens.—Where the plants for next autumn and winter-flowering cannot be accommodated in a house by themselves a hotbed should now be prepared in a cold frame. This is the best mode of bringing the plants from warm to cool treatment without receiving any check. The heat derived from a hotbed will assist them at first, and it will cool down gradually without a check to the plants, which is important if good well-grown specimens are to be produced. Young stock raised from seed at the commencement of the year, and still in pans in which they were pricked from the seed pots, may now be placed singly into 2-inch pots, and the hotbed referred to will be a suitable place in which to give them a good start. For a time after potting keep the frame closed, the plants moist and lightly shaded during bright sunshine. Good loam, a third of leaf mould, and a seventh of cow manure with sand may be employed for the compost. The leaf soil can be dispensed with when the plants are placed in their largest pots.

Chrysanthemums.—These are now sturdy plants in cold frames, and if propagated and treated as previously directed will be ready for placing into 6-inch pots. They still need cold-frame protection, for the nights are cold. After potting keep the frame close until the roots are extending, when more air may be given, and the plants grown as cool and hardy as possible, or they will become weakly. The lights should be thrown off during the day when mild, and should be left open all night whenever it is possible to do so. Those required for standards should be supplied with a small upright stake if they need it. The shoots of plants required for bushes should be pinched when necessary. Employ for potting good loam, manure, and sand.

Tree Carnations.—The blooms of few plants are more eagerly sought after during the winter and spring than those of Carnations, and to have them in good condition they require every care and attention. If rooted and placed into 3-inch pots as directed the young plants will have made a good number of roots, and may now be placed into 5 or 6-inch pots. If not quite ready leave them a week or two longer, but do not allow them to become root-bound, for if checked from this cause they may be ruined for the season. The pots in which they are placed should be drained

well and the plants potted firmly in good loam, leaf mould about one-third, and a seventh of cow manure, and a liberal dash of sand. Grow the plants in a cold house or frame, for these plants, like Chrysanthemums, will not bear heat.

THE BEE-KEEPER.

NOTES ON BEES.

VICIOUS BEES.

WHEN bees are accustomed to people and domesticated animals near the apiary they seldom offer an attack unless through some provocation, which they are sure to resent. Incautious manipulation, turning the soil, and pulling weeds or vegetables; certain odours, such as musk and other scents; vinegar and smoke, and allowing bees to have access to honeycomb or robbing other hives, are a few of the many things that irritate them, all of which should be guarded against. One bee irritated and using its sting may set the whole apiary in a frantic and vicious state, which may last for weeks ere they be calmed down. It is possible that bees possess a sense that we are ignorant of. One thing is certain, when people of a nervous temperament manipulate bees there is something that excites them. We can avoid irritating bees in many ways, such as by leaving the apiary for a time when they are inclined to sting or disturbing them as mentioned above; but there are times when all danger has to be faced, and caution with firmness is necessary, and veils if stings are dreaded. When manipulating I seldom either use a veil or smoke, carbolic acid being so much superior to the latter that it enables me to manipulate with safety, leaving the bees in a passive state after. The hive also is the better able to resist foul brood, while moths do not harbour where it has been used, neither is the honey tainted nor the larvæ affected by its use, as is the case when smoke is used. Carbolic acid is useful to prevent robbers attacking another hive. The attacking hive is well smeared at the entrance; this diverts the bees from making further inroads on its weaker neighbours. When commencing to manipulate, if the bees are vicious or suspected to be so, I smear the alighting board with some acid, then uncover the hive. I then smear the tops of the frames with the acid, and having a wing or feather also saturated so that I may dislodge the bees from any part by its use, placing it near the bees, causing them to retreat to or from any part I may choose. When this is done the bees remain quiet, and do not crowd over the frames nor attempt to sting as they do when smoke is used.

My hives have an advantage over other frame hives which renders them much more easily manipulated, while the hive is not exposed to draught and robbers, nor is the operator so liable to be stung. This advantage consists in having the tops of the frames fitted with lateral slides, so that there is no need to expose more combs than the one operated upon. These slides have the same value as in the Stewarton. By their use the hive can be insensibly ventilated. Draught is entirely obviated through brood nest when supers are on, and dispenses with excluder zinc, while they insure at all times supers free from brood. When using carbolic acid it is necessary to be very cautious, because if it touches the bees it kills them. As carbolic acid is of great service in the apiary in many ways a supply should always be kept on hand. Creosote has been long known for the same purpose, but the usefulness of carbolic acid in the apiary was first made known in these pages by that distinguished apiarian "R. S.," whose communications were much admired long ago by all interested.

REMEDIES FOR STINGS.

There are many applications and nostrums recommended for stings none of them being effectual as a cure, for the very simple reason that the poison has impregnated the system before the alkali can be applied and reach the acid to neutralise it. There is a lotion sold as a cure for stings, but unfortunately it is alum and water only, with a little scent added. Alum never will neutralise the poison of the sting of the bee. Some people are so little affected by stings that when they apply anything they imagine it to be a cure, then publish the same, thereby misleading others. I have had some very serious cases of stinging. The best remedy I ever found was to apply heat by steam or water to the patient to cause a free perspiration, and to give a little sal volatile; but this latter ought to be prescribed by the medical man. Not a moment should be lost to bring on a free perspiration, and every means resorted to that will accomplish that end.

EXHAUSTING QUEENS.

This very unfavourable weather, which has lasted since the beginning of April, has not only retarded the advance of hives but exhausts the queen, and will materially affect the prosperity of the hive. It is a fact that when once a queen is in condition for laying she deposits her eggs in the same ratio in bad weather as she would do in fair weather; but while they would be hatched and nursed in the latter case, they would undoubtedly be destroyed in the former; thus not only is the queen impaired, but the hive never attains the strength it would otherwise do. When hives are well supplied in the autumn with honey and pollen stores there is less fear of them suffering through the above, as they advance steadily with the season, but it is very different with those stimulated to unseasonable activity. With such hives, where there is so

much waste of eggs, the queens soon become (comparatively speaking) old, and should not be depended on for more than one season.

BEES NEAR-SIGHTED.

Some people are of the opinion that bees are not near-sighted—i.e. cannot discern an object near them. I cannot endorse that statement, as I have repeatedly observed when bees were feeding under a glass cover they started when an object was made to pass over or close to them.—A LANARKSHIRE BEE-KEEPER.

SYRIAN BEES v. BLACKS.

IN reference to the letter of "K. B. K." on page 293 it seems necessary to compare a few sentences, so that each reader may judge for himself as to whether some passages have not been read in the opposite to their natural meaning. Your correspondent says, on page 373, that I stated "£20 of profit had been obtained in one year from one stock of Syrians, while blacks did not gather enough to winter on." To this he says he remarked that the £20 quoted "could not be the one he knew of, as that was made in the year 1881, when all stocks did well." Now, compare what I did say on page 253. "I can cite a case where £20 profit has been made in one season in this country from one stock (hybrids); another where the increase was seven, and each gathered sufficient to winter on, while twenty black stocks failed to swarm and had to be fed for winter."

Next "K. B. K." on page 293, after asking for particulars of the £20 profit, says, "I have some recollections of a statement of the sort in print, but as I believe the bulk of the profit was derived from the sale of swarms or queens, and was, if I remember rightly, in 1881, when all stocks—black or yellow—gathered enough to winter upon." He presumes I refer to some other colony. This, however, is nothing to compare with his misleading quotation from the "British Bee Journal" on page 63, vol. ix. (not page 64, as he says) about small nuclei, swarms, and casts producing treble their value in honey, for in the concluding part of that article these words occur, "Notwithstanding the glorious weather here (Southall, Middlesex) in Scotland and Ireland there is not the same ground for satisfaction, reports of rain in Ireland almost daily and coldness being rife." This sentence is partly on pages 63 and 64, and concludes in fifty more words, so he must have seen and read it, and explains his giving 64 as the page.

Again, it will be noted, I did not say or imply that blacks standing in the neighbourhood of the stock which made £20 profit failed to swarm or secure stores for winter, but in connection with the one which increased seven, which was at Ulverston in North Lancashire, on the north of Morecombe Bay, between Scotland and Ireland. There is no excuse for him getting wrong, as I gave on page 353, in answer to "A. Tyke," the place where part of the account could be found, which is the very number that the £20 profit is published in, and in which the writer says, "The Syrian queen I had from you threw off five swarms in June, and the first swarm threw a virgin on the 18th of July, and a second on the 30th. . . . We had rain almost every day in June, July, and first three weeks in August. . . . It certainly has been the worst year for honey on record. . . . I have boiled eighteen stones of sugar this autumn to keep them alive over the winter. I had a few sections filled in May, otherwise there would have been none." In face of this and the well-known fact that in the north of England, Scotland, and Ireland 1881 was one of the worst honey years known, he tries to make it out to be the best, and that all stocks, black or yellow, strong or weak, did well throughout the United Kingdom just because they happened to do so in the south, and puts this forth to show the value of what I write, and concludes with the remark that "comment is needless."

If I have written anything to offend Mr. Doolittle I am prepared to answer him. I understand somewhat the subjects I write on, and take means to keep myself well informed, which was the reason I had a file of the "American Bee Journal" to refer to and verify "K. B. K.'s" quotations, which perhaps he did not expect. The word "Jarna" on page 352 should have been printed "Java."—HALLAMSHIRE.

TRADE CATALOGUES RECEIVED.

Edmund Phillip Dixon, 57, Queen Street, Hull.—*Catalogue of New and Choice Plants.*

W. & J. Birkenhead, Fern Nursery, Sale, near Manchester.—*Catalogue of Ferns (illustrated).*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We

request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Painting Hot-water Pipes (*Mrs. M., Kilkenny*).—Neither black varnish nor ordinary black paint is safe for applying to hot-water pipes in green-houses. A mixture of lamp black and linseed oil, however, will answer your purpose, and you may apply it at once.

Old Show Polyanthus (*R. C.*).—We are not able to answer your question. We presume the varieties you require are not very plentiful, or they would be procurable through florists. You mention Mr. Cannell. Have you written to him on the subject? There are many plants in nurseries that are not enumerated in catalogues.

Cropping Vine (*A Young Head Gardener*).—You appear to have acted wisely so far, but you may easily err by overcropping. It is impossible for anyone to say how many bunches your Vine may safely carry without knowing its condition. If it is growing freely and roots are plentiful near the surface of the border it ought to mature the crop to which you refer with the aid of manurial mulchings over the roots and the judicious use of liquid manure.

Flowers by Post (*J. P., Dublin*).—They should be placed in small wood or tin boxes with sufficient slightly damp and very clean moss to render them immovable. Damp cotton wool is also suitable, but very few flowers that are surrounded with dry wool reach us in a fresh state. A soft green leaf of any kind, such as Spinach, is much better for placing round the flowers than dry paper. There is sufficient moisture in the leaf without damping it when packing.

Special Societies (*Amateur*).—We have received a number of letters besides yours that have not been published, and for the same reason—that although the writers of them may not have intended to provoke replies of a personal nature, yet the communications would have had that effect. We have letters pertaining to the subject of "What is an amateur?" that will be published in due time.

Dahlias not Growing (*F. J.*).—By all means wait patiently, and especially as fresh roots are forming freely, as the probability is that there are latent buds that will be forced into growth. Occasionally, however, the buds are destroyed either by having been kept too wet or too dry, and then no growth follows, even if roots form freely; yet this is exceptional, and you had better, as you say, "give them time."

German Moss Litter (*H. S.*).—It has been advertised in the Journal by Gerhard Helmucke, 88, Bishopsgate Street Within, London, E.C., from whom you could doubtless obtain all the information you need. This material is very largely employed in horse stables, and afterwards as manure. It has been found good for making Mushroom beds, and also, as you will find from a letter in our present issue, is a good medium for Orchids in its natural state, and before being used in stables.

Designs for Carpet Beds (*Cambridge*).—We doubt if any better designs can be drawn than those that have appeared from time to time in our columns. There are examples suited for various shapes and sizes of beds, and they can be easily modified to suit individual requirements and to accommodate the particular plants that it is desired to employ. If you state the size and form of your bed, and the plants at your disposal, we can perhaps assist you in their effective arrangement.

Anemones Luxuriant (*A. Fitch*).—Your plants are attacked by a fungus, *Æcidium quadridum*, which is peculiar to garden Anemones. Attacks of parasites often induce a sort of spurious luxuriance. As little is generally known about the nature of this fungus a small engraving will be prepared and a description given. The fungus is a very curious one. It is a close ally of the old so-called corn mildew fungus of Barberry bushes. Destroy the affected plants.

Fruit not Setting (*W.*).—Pears and Plums in orchard houses require a very free circulation of air during the blossoming period, and an atmosphere sufficiently dry for liberating the pollen; it is well also to aid its dispersion by shaking the trees slightly when the blossoms are expanded. We suspect your house has been kept rather too close for these fruits, and possibly the trees grow too luxuriantly. The flower you have sent is of *Maguolia purpurea*.

Lilium longiflorum Harrisii (*S. L. B.*).—Do not repot the plants now, but encourage the growth as much as possible, either by a top-dressing of well-decayed manure or liberal supplies of weak liquid manure. Endeavour to insure a thorough maturation of the growth, and do not cut away the old stem until it is showing signs of decay. The better the growth the stronger will the bulbs be, and the more likely will they be to flower.

Sowing Hawthorn and Larch Seed (*A. B.*).—The practice in regard to the former is to gather the haws in the autumn and bury them in the ground for about eighteen months, and then sow them—that is to say, those gathered in October or November, 1884, would not be sown until February or March, 1886. Larch seed requires no such preparation. Your seedsman will procure some for you, and you may sow it in early spring.

Seedling Pansies (*Atherstone*).—Though the blooms before us are effective and the varieties are worth growing for decorative purposes, they are not equal to those named and sold by florists who devote special attention to these flowers. The best flower you have sent is a reddish maroon self, but as the blooms are not numbered we cannot refer to them individually.

Insects on Apricot Leaves (*A Constant Reader, Hereford*).—The disfiguring blisters are produced by the larva or caterpillar of a small moth, one

in the *Tinea* group, and apparently the species named *Coleophora hemerobiella*, which, though most frequent on Pear or Plum, also visits other fruit trees. As these larvæ live in little abodes of their own construction cut from the leaves, keeping all the body concealed if alarmed, they do not well admit of being dealt with by syringing, though some would be washed off the leaves. Professor Westwood states he knows no better method of dealing with the insect than careful hand-picking, and in the autumn all the dead leaves should be removed and burnt, since these would be sure to have attached to them some of the pupa of the insects. But we do not think, except in very rare cases this species does more than disfigure, it is not likely to affect the vitality of the Apricot.

Lawn Tennis Ground (*A. K., Blackheath*).—In reply to the question of a correspondent Mr. R. Inglis wrote as follows some time ago in the Journal:—"The regulation size of tennis courts is 78 feet by 36 feet. Outside this there should be at least a yard all round, but better if it is two—namely, 85 feet by 42 feet of level lawn. Tennis lawns are generally made quite level, which I think is a mistake, especially if the soil is of a stiff moist nature. It is much better if the ground is kept a little higher in the centre, say 4 or 5 inches, so that when a heavy rain occurs much of it passes off to the sides and ends, and the ground is quicker dry and fit to play upon sooner than when made perfectly level, and the greater part of the rain having sunk into the ground. It is very essential to have a firm surface; and for this reason, where the soil is clay or is wet, it is a good plan, after having levelled and consolidated the ground, to spread about an inch of clean coal ashes over it before laying down the turf. In addition to this it should be previously well drained. On light dry soils less trouble is necessary to have a fair tennis lawn; indeed, it may be played for 'home practice' on any lawn where there is a little less room than is required for full-sized courts, and although it is not quite level."

Heating Vinery (*H. S.*).—A flow-and-return 4-inch pipe will be quite sufficient to heat the house, having them on the lower side of the house, but preferably along both sides, the flow on one side and the return on the other, which will give you a more equal diffusion of the heat; but as this will cause the pipes to be taken all round the house it may be inconvenient in your case, as the doors are probably at one or both ends, and it is important that the pipes be kept clear of the soil, or their heating power will be considerably reduced. We do not think the Polmaise system of heating at all equal to heating by hot water with, for a small house, an ordinary saddle boiler.

Muscat of Alexandria Grapes Shank (*W. L.*).—The chief cause of shanking is defective root-action, the roots being deep or in a border of close material imperfectly drained. As the Vines crop well they may have been simply overweighted. There may not be anything wrong with the border as regards material and drainage, but unless satisfied on that score we should make an examination of the roots in the autumn, or as soon as the crop is cleared, and if anything be found wrong rectify it without delay. As regards the present crop, we should allow the laterals to extend as far as space admits without crowding the principal foliage, so as to deprive it of light and air. This will encourage root-action, which should be induced near the surface by watering with tepid liquid manure and mulching the surface of the border with good partially decayed manure. A good soaking of water when the Grapes commence ripening will mostly be sufficient to carry the Vines through until the crop is finished off; but if there be any deficiency of moisture in the border, in ten days or a fortnight afterwards give another soaking, always employing tepid water, and if done early in the day time will be allowed for the passing-off of superfluous moisture before nightfall. See that the crop is not too heavy, as shanking frequently results from that cause alone, and sometimes from a deficiency of lime in the border, especially in those rich in humus or deficient in calcareous matter. A bushel of quick-lime per rod of border spread on the surface and pointed lightly in will in most cases of this kind prove highly beneficial. The best time to apply the lime is a little prior to starting the Vines. Bone bust is also useful as a surface dressing, and may be applied now, but preferably at the winter surface dressing.

Packing Strawberries to Send by Rail (*Idem*).—We submitted your inquiries on packing fruit and flowers to a very experienced gardener, who replies as follows:—"Shallow deal boxes about 1½ inch deep are most suitable, so as to hold a single layer of fruit, and they may be of any size in other respects as the quantity to be sent may determine. Ours for sending from the country to the family in London daily are of half-inch deal, 12 inches long and 11 inches wide, and any number travel safely placed one upon the other and securely tied together with string. We pad the bottom of the box with a layer of Vine or Spinach leaves, gathered a short time so as to become limp, and then place the Strawberries in the box with the stalk downwards, enclosing each fruit in a Strawberry leaf, and placing rather tightly so as to prevent moving about, and keeping the fruit sufficiently low so as to prevent crushing by the lid, which is placed down on a layer of leaves as at the bottom."

Packing Cut Flowers (*Idem*).—"We use deal boxes for these, about 18 inches long, 15 inches wide, and 3 or 4 inches deep. A little damp moss is placed at the bottom, the moss being washed clean and all the water squeezed out. The sides of the box are then lined with clean white paper, and the flowers are put in in layers, the heaviest at the bottom as well as the heavier fronds of Ferns, and the lighter flowers at top, with *Adiantum* spread all over the flowers. A very light sprinkling of water is given—just a few dashes of the fingers after being dipped in water, then covering with a double thickness of tissue paper before putting on the lid. Any number of boxes can be tied together, and with the address label on the upper side they travel safely. The flowers should be packed rather tightly, but not squeezed down and crushed, as is often the case, and should be gathered in the early part of the day, as they are then much fresher and fuller of moisture than when the day is advanced. For sending by post we use tin boxes, lining with cotton wadding and wrapping the flowers in tissue paper, so as to keep them from the wool, for when the flowers are in contact with it the moisture is rapidly absorbed from the flowers. They should be packed so that they cannot move about, or they will be so damaged as to be useless."

Grapes Scalded (*J. W. H.*).—The Grapes you have sent are what is known as scalded, and the Vines, according to your description of them, are

scored. You have stated quite sufficient to account for their unsatisfactory condition. The pipes to which you applied sulphur have probably been hotter than you represent, although you were not there to test them. It has frequently been advised in this Journal that sulphur when needed to check the increase of red spider should be first applied to the return pipes, as being cooler, and hence safer, than painting the flows; yet you have painted the "upper side" of what we presume are the flow pipes. If the pipes were not hotter than you state the temperature has been too high by sun heat before air was admitted. Then the "strong stable manure" has in all probability contributed to the evil of injured foliage and fruit. An excess of ammonia in the atmosphere when the growths of the Vines are young and tender is decidedly injurious, and the danger is aggravated by keeping the house too close, as we feel confident you have done both by night and by day. Under the circumstances when you found the manure so strong you ought certainly to have left the top ventilators of the house open all night, and admitted more air very early in the morning; and further, if the days were bright, shading should have been resorted to when you found the air impregnated with sulphur and ammonia. Over and over again has the necessity for such precautions against injury been pointed out, still their full importance do not appear to be appreciated by all readers until they find by experience that they cannot be safely ignored. You can only act in accordance with the advice suggested of night ventilation as a safety valve, and very early admissions of air in the morning, and if this system fails then have recourse to light shading, regarding it as the lesser of two evils, the greater being injured Vines.

Various (Aurora).—The white flower you have sent is *Iberis coriacea*, one of the best of the perennial Candytuft, and most attractive in gardens during the spring and early summer months. Young shoots just getting a little firm, but by no means hard, inserted in firm and very sandy soil under a Landlight, keeping them moist and shaded to prevent flagging, strike freely. Growth a little softer, as just cutting crisply, inserted in a pot, and covered with a bellglass, strike more quickly in a warm frame, where, however, they must not remain a day after they have rooted and are starting into growth. The yellow flower is *Cheiranthus Marshalli*, and may be propagated in exactly the same way. Cuttings rooted under handlights perhaps make the most sturdy plants, but everything depends on the skill of the propagator. As the Rhubarb is newly planted by all means water it regularly in dry weather, and it will probably commence growing freely as the season advances. The stalks should be pulled when wanted. Possibly your Rhubarb has been "cut" too closely. No stalks should be used until the plants are strong, and the more leaves you allow to develop and mature the stronger will be the crowns and the more abundant the produce.

Vines Withering (Constant Subscriber).—So many examples of injured Vine leaves are sent to us that it is impossible for us to remember the exact nature of every case after it has been attended to. It appears we stated that the leaves you sent were scorched. In reply you say you "know to the contrary." There is thus a conflict of opinion, and the question arises not only as to whether your experience is greater than ours or not, but whether you or ourselves have the better facilities for forming a correct opinion. If you had subjected the leaves you sent us to close examination under a powerful microscope, you would have had plainly revealed to you their real condition, and we venture to say it would not have been "quite the contrary" of what we stated. The small portion of lateral you have now sent has no scorched leaves, nor is the specimen at all sufficient to enable us to account for the withering of the shoot, while your letter contains no information to guide us to any conclusion on the subject. You say nothing about soil, temperature, watering, or atmospheric moisture—in fact you do not give the slightest hint regarding the treatment to which the Vines have been subjected. We do not give answers by guesswork, but found our replies on the evidence that is either supplied or is apparent in each case. You allude to the shoots being "poisoned," and that cutting out the affected parts and applying lime is the antidote. We are glad the malady is under your control, and you cannot do better than apply the remedy you find efficacious. The nature of the "poison" we have absolutely no means of determining; it may be a form of gangrene arising from too much nitrogenous matter in the soil, or from some error in ventilation, or an excess of root or atmospheric moisture. We are very willing to aid you if you will supply us with more data for doing so than your hurriedly written letter affords.

Mildew on Vines (J. O., Monmouth).—We regret your Vines are seriously infested with mildew, not only the bunches but the leaves with their foot-stalks being infested. However, you have checked the parasite on the foliage, and in many places destroyed it by the syringing with Gishurst compound, but it is increasing rapidly on the berries. Mix some sulphur with the water, and give another good syringing, and if it does not adhere to the berries dust the bunches well with sulphur. It is often difficult to prevent the attacks of mildew in houses so crowded with plants as yours are. You cannot do better than maintain your present temperatures, and keep the atmosphere of the house drier if possible, never closing the top ventilators, and at the same time admitting more air very early or immediately the sun reaches the house, and do not close early in the afternoon with much moisture in the usual manner. A moist and close atmosphere favours the growth of the parasite, one dry and buoyant checking its increase; yet sharp currents of air must be avoided, as you have evidence of their effects in the mildew being worst near the door of the house. Painting the return hot-water pipes with sulphur would have a tendency to check the increase of the destructive pest.

Cucumbers and Melons Withering (W. B. B.).—The plants either do not receive sufficient support or the atmosphere of the house is too dry, the latter being perhaps the most probable cause of the unsatisfactory condition of the plants. Apply water copiously to the roots—that is, pour it into the soil so long as it passes away freely, and if the roots are plentiful give soot water twice a week. Also surface the bed with rough rich soil as often as fibres are seen protruding through it; syringe the plants freely, yet carefully, twice a day; have troughs on the pipes filled with water, damp the paths, walls, and bed frequently, admit air by the top ventilators only, and your plants will be bound to grow. When we say open the top lights only, it is of course on the assumption that by opening them early and increasing the

ventilation in advance of the desired temperature that a maximum of 85° will not be exceeded. Opening the front ventilators of Melon and Cucumber houses needlessly is very common, and results in the drying of the air and causing so much moisture to evaporate from the leaves that they collapse. We think if you work on the lines indicated your plants will improve, unless, indeed, they are exhausted beyond recovery.

Tomatoes Destroyed (D. B.).—Judging from the description given, your friend's several losses of Tomato plants have been caused by wireworms. If you had forwarded part of a damaged stem with insect enclosed it would have simplified our answer. A rather large specimen of wireworm we have before us measures about 1 inch in length, is one-quarter of an inch in circumference, of a rich yellow colour, and has three pairs of legs disposed near the head. They are wonderfully destructive and very difficult of eradication. Your advice to clear out all the old soil and restart with fresh was the best that could be given under the circumstances, especially seeing how little soil Tomatoes really require. A small square ridge of soil, about 18 inches wide, and the same or less in depth, enclosed with either a loose brick wall or turves, is ample to start with, occasional top-dressings being given as the plants gain in strength and are bearing freely. As your friend objects to remove the old soil, his best plan will be to carefully turn the heap, picking out all the wireworms that can be seen. In order also to encourage rapid growth of the Tomatoes, and in this manner escape entire destruction, it is advisable to mix some kind of artificial manure or guano with the compost at the rate recommended by the vendors. Failing this a sprinkling of soot and common salt would prove similarly beneficial. As the wireworms collect near the underground portion of the stems, these should not be buried deeply, in order that they may be frequently bared and the wireworms discovered and destroyed. Petroleum at the rate of 2 ozs. to a gallon of hot water, and kept well stirred with a syringe to prevent its collecting on the surface, if syringed when cool enough on to the lower portion of the stems and allowed to run down to the roots, will act as a deterrent, without, however, actually destroying the wireworms or injuring the roots. Pieces of Potatoes or Carrots attached to stakes and plunged into the soil will entrap some of them, and should be occasionally drawn out and examined. Soil that is known to contain grubs should be scorched before using; this increases its fertility and destroys all pests.

Names of Plants (J. H., Sussex).—The Banksian Rose, *Rosa Banksiae*; (*Constant Reader*).—1, *Kerria japonica flore-pleno*; 2, *Stachys lanata*; 3, *Staphylea colchica*; 4, *Muscari moschatum*. (*Subscriber*).—1, a variety of *Ixia*, but it was too much withered to be recognisable; 2, *Spiraea prunifolia*; 3, *Cephalotaxus drupacea*; 4, *C. Fortunei*; the green flower is *Ixia viridiflora*, the other is *Ixia cæteroides*. (*A. D. H. C.*).—1, insufficient for determination; 2, *Acorus Calamus*; 3, *Rhododendron cinnabarinum*. (*W. M.*).—*Carex pendula*. (*H., Constant Reader*).—2, *Saxifraga granulata flore-pleno*; 4, *Lastrea Filix-mas cristata*; 5, *Adiantum pedatum*; the others were insufficient.

COVENT GARDEN MARKET.—MAY 21ST.

OUR market still heavily supplied, with business exceedingly quiet. Prices bearing downwards, Cucumbers alone maintaining former values.

THE SHROPSHIRE BREED OF SHEEP.

(Continued from page 396.)

An important period in the history of the Shropshire breed must now be referred to, and for a time the higher-bred and shorter-woolled stock seem to have carried everything before them for a considerable number of years, but more particularly the sheep bred at Latimer, the property of the late Lord Chesham. At the Bedford

Royal Agricultural Society of England's meeting in 1874 Lord Chesham took the first prize in the large class of ninety-six shearling rams. In the aged ram class, with twenty entries, he took the third prize; but in the class for shearling ewes his lordship's entry took the first prize in a class wherein one hundred sheep were shown. This was an important victory, and proved a true presage of great renown for the Latimer flock. We will make a quotation from the Judges' report on that occasion:—"As compared with previous exhibitions, which we have observed for fifteen years, we consider the classes contrast favourably, especially taking into consideration the number of the general entries. As a whole we find the sheep possess more uniformity of character, have not diminished in size, and still maintain the muscular proportions and consumable material which are themselves the natural properties of the Shropshires; though we wish to remark that there were specimens exhibited to whose character we take exception, and whose breeders we advise to exercise a strict attention to type and colour." Here we wish to remark that a spirited exhibitor, Mr. T. J. Mansell, took the second prize only in the shearling ram class; but in the aged ram class he took the first prize, in which class Lord Chesham took only third prize, thus showing that Mr. Mansell was such an enterprising exhibitor that we may naturally expect that he possessed a type and style of sheep destined to make a great advance in the Judges' estimation and favour at a future time, when early maturity and

as it is termed. Out of this discussion, too, came the conclusion that dark points of uniform colour, with the largest possible size of frame, were the correct objects to arrive at. The more experienced and consistent breeders came to this conclusion among themselves about the time of the "Royal" Battersea Show in 1862, and most admirably have they carried it out by their skill in the art of selection.

As an illustration of the best style of Shropshire sheep above referred to, we give a portrait from the *Agricultural Gazette* of August 29th, 1881, of Mr. Mansell's first-prize Shropshire ram, Dudmaston Hero. The portrait is a very successful sketch by Mr. A. M. Williams from a photograph taken at Derby by the Animal Photograph Company of Mr. W. Mansell's ram, aged two years and four months, sold to Mr. R. Loder, M.P., at Mr. Mansell's sale for 200 guineas.

The last quotation, together with our previous quotations from the Judges' reports, shows that a contest of the greatest importance had been going on as between the character of sheep bred by Lord Chesham and those bred by Mr. Mansell. It is, therefore, interesting to see the result of this contest as exemplified by the report of the Senior Steward at the "Royal" Meeting of York in 1883, and also the Judges' report on the classes of Shropshire sheep. The first report states:—"The judging of the ninety odd entries of Shropshire rams, for instance, was a severe task for the Judges, but the gentlemen in office bestowed great care and no little time on their duties. The two-shear class was not so large nor so difficult to judge. Here

Fig. 95.

weight for age was likely to be the leading object of breeders of this breed of sheep.

From the period of 1874 up to 1881 the Shropshires continued to show some diversity of type and character; but the general success of the Latimer flock, which in the hands of Lord Chesham's shepherds and agents assumed almost a pure Down style during the whole of this time, and generally taking a large portion of the leading prizes. But some competitors had different objects in view, and a want of uniformity was still conspicuous, and we glean from a statement in the *Agricultural Gazette* for August 29th, 1881, as follows:—"Judges at shows of course also differed in opinion. One or two out of the three were in favour of the South Down colour and type, while the next year two were in favour of dark colour and more size, notwithstanding the legs of the sheep were a little longer, and that the latter required more cake and corn to mature them early, or more time to get them fat in the ordinary way. The advocates of the latter argued that there were several breeds of small sheep, some of which were deficient in flesh as compared with the fat they produced. Upon this they said, "We have in the Shropshires large frames and ample lean of a dark rich colour. The smaller Down-like frames must be discarded, and the larger sizes cultivated." The results, as seen at the present time, have clearly proved that the latter advocates were right. This conflict of opinions and diversity of taste led to warm discussions. It was shown that in more than one instance pure South Downs had been introduced into flocks of the established Shropshire stock. In each instance the flock "went all to pieces,"

Mr. Thos. J. Mansell brought further honour to the Dudmaston flock, his beautiful and rarely covered little sheep, which was first in a monster shearling class at Reading in 1882, and whose letting price last season was 165 guineas, came out to try his fortune again in company with a more lengthy sheep from the same flock, but bred by Mr. C. Wadlow, Bridgenorth. The pair were invincible. The Judges gave the preference to the greater size and gaiety displayed by the Bridgnorth sheep. Ten of the ninety-two pens for shearling rams were empty, but there was ample material left to perplex the Judges. Lord Chesham's pair, bred in the old Latimer flock, accomplished a wonderful performance, having taken both first and second prizes. The first was as ripe almost as a pear; on the back he handles charmingly, his rump was neat and well covered, his head attractive, bone fine, and character perfection. Since then he has been purchased by that good all-round judge, Mr. Randell, at 100 guineas. The sire of the first shearling was Dudmaston, a celebrated sheep of Mr. Mansell's breeding. The second, whose sire was also Dudmaston, is bigger than the first, but he is not quite so plump and full of quality. Several other sheep noticed in the same large class were sired by a Dudmaston sheep. Shearling ewes are reported if not so large an entry as shearling tups, were nevertheless very fine and nearly uniform in type and quality. Lord Chesham's Reserve gimmers were very sweet, and ten good pens were commended."

The Judges' report says, shearling ram class:—"It gives us great pleasure to bear our testimony to the excellence of this grand class

of sheep, represented by eighty-seven entries. The first and second-prize animals show beautiful form, and have well-covered frames. We felt it our duty to highly commend and commend no less than sixteen entries."

These quotations were not only necessary to prove the advance of this breed, but also the direction in which the advance had taken, and it will be seen that Lord Chesham is still the foremost prize-winner in the ram classes, but that to enable him to do this he has engrafted or sired on the old Latimer high-bred stock with sheep from Mr. Mansell, owner of the Dudmaston Hero. This shows in the most singular manner the discrimination and sound judgment of Lord Chesham in having improved his old breed to meet the new views entertained by the judges and practical farmers on the point of increased weight for age, and this is most certainly the tenant farmers' view of the requisite in rent-paying sheep. In this matter, however, the consumer's view is rather lost sight of, for there can be no question the nearer approach these sheep make to the South Down character that the better quality they yield as mutton, because the lean meat not only prevails and is better mixed or marbled, but that the joints are more moderate and selling in size, whereas the stock showing more of the long-woolled style and growth make heavier weights for age and prove more valuable, although coarser in flesh, as food for the million.

Whilst keeping in view the interest of the home farmer and tenant farmer we have yet to notice a matter of the highest importance, and which has been the subject uppermost in the minds of practical rent-paying farmers for some years past—viz., the tendency to twin in certain breeds of sheep. Certainly it is most desirable not to lose sight of the per-centage of lambs reared from different breeds of sheep, for although it has been generally acknowledged that the horned Dorset and Somerset breeds produce more lambs than any other stock to be found in the southern and south-western counties of England, yet it is of equal consequence to the flock-masters of the midlands also to possess a breed which will yield the largest number of twin lambs. A correspondent of the *Agricultural Gazette* on November 12th, 1883, says:—"Allow me to inform you that after thirty-five years' experience in the breeding and management of several breeds of sheep—South, Hampshire, Oxford Downs, also Lincoln and Cotswold crossed with Leicester, I have come to the conclusion that the improved Shropshire is the most prolific and rent-paying animal for general purposes to be found in this country at the present time. They are adapted for both high and low, heavy or light soils, will do well on grass or plough, and stand more hardships than any other class of sheep bred in England." As an illustration of the per-centage of lambs obtained from Shropshires, we take the returns from nine different breeders that 1075 ewes produced on the average nearly 122 per cent. of lambs.

WORK ON THE HOME FARM.

Horse Labour.—Horses are still actively engaged in preparing the land for the seed of root crops. This preparation on the arable farms connected with dairy farming may well assume a revolutionary form, for the points to which we referred last week—that is, the wider drilling of both Mangolds, Swedes, or other root crops to be removed for feeding at the homestead or even on pasture land, will commend itself to a host of practical farmers. Many will see at a glance not only the great importance of growing roots wider apart for facilitating the interculture, but also the benefit to be derived from growing a crop of common Turnips between the main crop of roots to be removed; and it must also be understood that the Turnips, which will consist chiefly of foliage, are valuable to be ploughed-in, together with the leaves of the root crop removed. At the same time the main root crop will be produced without extra manure will be a full acreable tonnage, because if the same quantity of manure per acre is applied by the drill as usual, yet being applied to fewer drills, the manure will be more powerful in effect, and result in either larger roots or more of them, thus maintaining the full weight of the crop, and undiminished by the growth of Turnips between the drills. The early-sown roots will receive the full benefit of the start and first seeding, whereas the Turnips will benefit by the assistance afforded by the application between the drills of 2½ cwt. of mixed nitrate of soda and bone superphosphate per acre sown by hand. Upon many farms it will be found very convenient to make use of the hand-drill used for small seeds in gardens, and particularly it is useful for the drilling of Carrots, as follows:—Make the ground very fine, and sow the manure—say, 2 cwt. or 3 cwt. of bone superphosphate and guano, mixed together, will make a full dressing of 4 cwt. or 6 cwt. per acre sown broadcast, and then throw two furrows together formed into stretches, which will deposit the seed nearly in the centre of the stretches, then drill the seed on the top directly over the manure. In this way we have grown not only full crops of Carrots, but also Swedes, Turnips, and Mangolds, and in this way the interculture is greatly facilitated at and during any age or size of the young plants.

Hand Labour.—Weeding by the women or old men must now be done except in corn where Charlock prevails, in which case Koldmoo's weed-eradicator, drawn by a horse, will prove very effective if used at the right time—that is, just as the weeds are blooming. Hoeing Beans and Peas should now be finished as soon as possible, especially where the

Peas are drilled close in the lines, or in case of Beans and Peas being drilled together in the lines. Cutting Clovers and grasses in mixture will now be going on, especially where Trefoil or Hop Clover and Rye grass is grown. But under the new system of seeding the red Clover or Cow Grass Clover, both of which will yield a successional growth in accordance with our requirements. As the coarse pasture grasses are now mixed with them in alternate husbandry, such as Cocksfoot, Timothy, and Foxtail, we recommend that the crop should be cut much earlier than usual, looking more than ever to the production of the most nutritious hay, as well as the successional growth; for it is now easy to grow three crops in succession if the first is cut on or about the 1st of June. The object of three cuttings is very important, but especially so on those farms where green manuring prevails, and where young cattle or dairy cows are kept, the latter being fed with Clover twice a day at the time of milking, the former to be kept under cover and feeding for "baby beef." In this way by feeding either steers or heifers good beef can be made with a fair allowance of cake—say 3 lbs. per day, and a fair allowance also of green Clover, cut and given daily. The cattle sold from their boxes, having never been off the straw, at from twenty to twenty-four months old, and the result, both in beef and manure, we have proved to be a profitable system, for neither ensilage or hay is necessary, as our cattle in the winter months never get hay, but straw only, with roots and cake and bean or barley meal. The advantage of three cuttings or growths is very important, for when cut young the Clover and grasses make the highest quality of hay or ensilage, or cut green for the summer feeding of cattle. The benefit in the case of green manuring is also extended, for the third growth will be much greater of the grasses named than of Clover and Rye grass, and will prove highly valuable if ploughed-in as a manure for the succeeding Wheat crop. This method of cutting the Clovers for the soiling of horses and cattle will pay well for the labour, for our plan has always been that one man with the odd horse or mule shall cut and carry to the stables, as well as cattle boxes, all the green fodder required; and we repudiate and ignore the usual custom for the teammen to cut and carry the green fodder required for their horses daily. We then find under our plan there is no necessity for horse labour being hindered at haying or harvest, or at ordinary times when a couple of hours extra of horse labour during the summer season on particular occasions is a matter of economy and of benefit not to be obtained under ordinary farm management of the teams.

Live Stock.—On the hill farms, in fact on any occupations where sheep stock are kept, the summer feeding is now entered upon, and several changes each day are advantageous, especially on those farms where breeding flocks are kept, for it is a good plan, where the ewes and lambs are fed on grass growing on the arable land, to change from grass to Vetches, both being hurdled off into folds for ewes and lambs. The lambs being trough-fed will quickly get fat, especially if a few Mangolds are cut by Gardner's cutter and mixed with cake or beanmeal, or both, and in this way the lambs will be maintained in first-rate condition either for sale as wether lambs or as fat sucking lambs for the butcher. It is merely a difference as between cake and beanmeal for the latter, and a moderate allowance of beanmeal only for the former, in either case it being mixed with roots cut small and served in the troughs twice a day. All the pastures for grazing bullocks for beef in the autumn may now be stocked, but the best plan for such a proceeding is to purchase the cattle in the autumn, and winter them in the yards and sheds, so that they may be in health and sleek condition on being turned out this month to graze until fit for the butcher. It must, however, be carefully considered as to whether the pastures are of sufficient power to feed the animals fit for the butcher from their produce alone, otherwise where they are at all doubtful some cake—say, 3 lbs. each daily, may be given in troughs, with Mangolds cut and mixed with the cake.

REMARKS.

- 11th.—Extremely fine, hot, and almost cloudless. Several white butterflies.
 12th.—Fine; distant thunder 4 P.M., thunderstorm 4.30 to 5 P.M., with 0.15 inch of rain in less than half an hour; fair afterwards, but lightning till 10 P.M.
 13th.—Fine throughout, but cooler.
 14th.—Breezy and dull in morning, shower at 2.30 P.M.; fine evening.
 15th.—Dull, windy, and cooler.
 16th.—Generally dull, but hot sun at intervals.
 17th.—Very fine throughout, and cloudless in evening.

A fine summer-like week; temperature about 6° above the average.—G. J. SYMONS.

LIQUID AND ARTIFICIAL MANURES.

PLANT-FEEDING is practised in many gardens in a most careless manner, and cannot be too strongly condemned. Frequently liquid manure is poured into the pots of plants, or on to the beds of Melons and Cucumbers, long before they need any assistance, and instead of this benefiting the plants the soil is poisoned and failure incurred. It would indeed be difficult to point out any operation in the whole range of gardening that is carried on with such recklessness. I have for some years tried to have it performed on a judicious system; but with the most careful instructions, and every effort to insure that the orders given were properly executed, I have had plants ruined by carelessness in this respect. This led to the adoption of an entirely different method, which up to the present has answered well, and entails considerably less labour with scarcely any risk; and fortunately this plan is as simple as it is effectual.

I do not intend to detail the system of plant-feeding by liquid manure that has become so general, but proceed at once to the system of feeding on the surface by the aid of artificial manures. There are many of these prepared for plant food, and have proved to be of importance. Since the old system has been discarded I have had the most beneficial results. In the end the cost is very much less than when guano and other preparations have to be purchased for use in liquid form. Some of the liquids made from cow and sheep dung or the drainage of stables have an odour which is most objectionable. Artificial manures applied to the surface are clean and free from this disadvantage, besides effecting a wonderful saving in labour. Suppose 500 Chrysanthemums in 10-inch pots require feeding; a man will apply a fertiliser to the surface, which will be ample for at least a week, in the same time that he would prepare liquid manure sufficient for one application. This is a clear gain, and the good condition of the plants is insured because it can be seen at a glance that the required assistance has been given according to orders, and that instructions have been carried out, for the workman leaves his mark behind him.

I have largely practised this surface-feeding for plants of various descriptions; for Azaleas and Epacris no other system should be followed. The whole of our Gardenias are assisted in this way, with tree Mignonette, Primulas, and many others. These have all shown a marked improvement. Mignonette is rather impatient of strong supplies of liquid manure, but light applications to the surface have kept the roots in constant action, and fine spikes have been produced. Primulas flowered and continued longer under this system than formerly; while Roses, both in pots and planted out, have had no other assistance than upon the surface occasionally, and they have never grown with such luxuriance during the forcing season or produced more or better blooms. Adiantums and other Ferns thrive admirably under this system, growing most satisfactorily and producing deep green fronds.

Surface-feeding has not been entirely confined to plants, for French Beans in pots and planted out have had no other aid than one or two applications to the surface after feeding became necessary, and the result has been all that could have been desired. Cucumbers and Melons have also been treated on this principle, with marked benefit to the plants and crops.

The greatest effect has shown itself in the case of Strawberries, for all who have seen them have been struck by the rich deep colour and large size of the fruits, and above all their excellent flavour, the variety being Vicomtesse Hericart de Thury. Of this variety I have grown nearly 1000 plants annually, and had the plants finer, and to all appearance better ripened, but in size and quality the fruits were never equal to those gathered this year; the most remarkable fact of all being that the flavour was equally good when the fruits were gathered from the warm moist forcing house as from plants in cooler structures. The only difference in cultivation has been the surface-feeding. The plants were top-dressed with rich material when introduced to the forcing house with a little artificial manure mixed in the compost, and after the fruit was set two applications were given between that stage and the ripening of the crop, these proving sufficient.

On several occasions I have referred to Grapes grown in pots as well as Strawberries being invariably deficient in flavour if feeding was continued into the last stages of development. This is one reason I have in favour of placing Vines into larger pots than those in which they have been grown, so that they are not dependant upon the waterpot. It has been proved again and again that if Strawberries are fed until the fruit is ripe the flavour will be sadly deficient. This led me to the belief that artificial manures were capable of supplying Strawberries with food in a more substantial form, which would benefit them in their last stages and not endanger the flavour. Practice so far has confirmed that belief with the most satisfactory results, and this system of manuring will be continued.

There remains one more point in relation to feeding with artificial instead of liquid manures which is by no means an unimportant one. When stimulants are supplied from the waterpot seldom indeed do the roots come in numbers to the surface; on the contrary, the soil after a time has a sour appearance, and the roots have a tendency to grow downwards. When the surface soil is dressed with artificial manures it remains in a sweet condition, and the roots find their way there in large numbers. This activity of the roots on the surface is particularly noticeable in the plants and fruits which have been mentioned, and that is what good cultivators always like to see.

The method of sustaining and invigorating plants is now more largely practised in nurseries than formerly, because it is not only the safest but most economical system; also in those great establishments where plants are grown by the million for supplying the markets top-dressing with artificial manure is almost exclusively adopted, and it is questionable if better examples of culture can be seen anywhere than in the plants thus supported. It is quite astonishing to see how much can be got out of a small pot by a judicious system of top-dressing, and the same plan is being increasingly adopted in large fruit-growing establishments. This certainly would not be the case if it was not found advantageous, for it is incumbent with persons who are engaged in commercial horticulture to obtain the greatest possible return with the least possible outlay in material and labour; and hence it is that they adopt the plan that I have endeavoured to describe, and which I have not found wanting.

I shall not recommend any particular artificial manures. First, because I do not care to advise the use of particular articles sold by vendors in preference to those of others; and, secondly, because what might suit best here might not

suit in another garden with different treatment and dissimilar soil.—WM. BARDNEY.

OUTDOOR CULTIVATION OF THE STRAWBERRY.

THERE is no doubt that many Strawberry plantations are relied on annually for the crop, when it ought not to be counted on as profitable for more than two or three years. As the time will soon arrive when there will be abundance of runners, it will not be inopportune to give a few notes regarding the outdoor cultivation of the Strawberry. Many gardeners make their new Strawberry plantations in the autumn, others leave it until the spring; but we think a full crop ought to be procured the first season after planting. Therefore we will recommend the runners to be planted in their permanent quarters from the last week in July until the end of August. The sooner the runners are planted the stronger will be the plants, consequently there will be a larger crop of fruit. This system of Strawberry culture is well carried out by Mr. Douglas, Great Gearies, Ilford, and better results could not be obtained. Preparing the runners and preparing the ground for their reception ought to be attended to at about the same time, for as soon as the runners are well rooted they should be planted out.

PREPARING THE GROUND.—The ground should be well trenched to the depth of 30 inches, placing a good layer of decayed manure in the bottom of the trench, and another layer within a foot of the surface. If the subsoil is not in very good condition it must not be brought to the surface, but be kept underneath. It must be well worked up with some manure. After the ground has settled down it will be ready for the prepared runners.

PREPARING THE RUNNERS.—As soon as runners are obtainable they should be layered into 60-size pots, filled with a compost of four parts loam and one part decayed manure. The loam should be well divided and the manure sifted. If it is not convenient to use small pots, pieces of turf 4 inches square are good substitutes. Pinch the points off the runners before layering, as it will strengthen the remaining runners. Press the base of the runner on the surface of the soil or turf, and peg it in position. After being layered they must be kept well supplied with moisture. When well rooted sever them from the parent plants, stand them together in a sheltered place, and keep them well supplied with water. In a week they will be in good condition for planting out.

PLANTING OUT THE RUNNERS.—Two feet apart in the rows and the same between the rows is a good distance. To every plant give a good shovelful of soil, the same as was used for layering, only it may be in a slightly rougher state. Press the soil well round the roots, and form a shallow basin round them. Keep all runners removed as soon as they appear, and well water them every alternate night, or according to the weather. They will soon commence growing, when the Dutch hoe should be used frequently amongst them. As the season advances and the autumn rains come on discontinue watering.

AFTER-TREATMENT.—If the winter is likely to be severe mulch with some short dry manure. If it is likely to be an open winter do not mulch them, but use the Dutch hoe freely. After the fruit has set, and if it is dry weather, a good soaking of sewage or liquid manure should be given, afterwards well mulching them with long stable litter, which will soon become bleached and be a good protection for the fruit, otherwise clean straw can be used. It will well repay the cultivator if time can be spared to support the fruit with Birch branches. This is the best protection from slugs, and the fruit is kept clean.

SECOND YEAR'S TREATMENT.—After the fruit is gathered and all runners taken off that are required, remove the runners that are left with the old mulching. Well hoe and clean the plantation, and give a thorough dressing of well-decayed manure. This is all the treatment they will require beyond hand-weeding and cutting off any runners which may appear until the fruiting period arrives, when the protection of the fruit must be seen to.

If a new plantation is made every year it will be much the best system, as then there will be a one-year and two-year-old plantation in full bearing; but the one-year-old plantation will produce much the finer fruit.

VARIETIES.—Most gardeners have their favourite sorts, but I give a short list for succession:—Vicomtesse Hericart de Thury, Keens' Seedling, Sir Joseph Paxton, President, Sir Charles Napier, British Queen (in some soils), Unser Fritz, Loxford Hall Seedling, Frogmore Late Pine, and Oxonian.—A. YOUNG.

FLORA OF THE PHILIPPINE ISLANDS—At the recent meeting of the Linnean Society Mr. R. H. Rolfe of the Kew Herbarium gave a communication on the flora of the Philippine Islands and its probable derivation. According to recent computation the phænogamic vegetation of the Philippines consists of 3564 species belonging to 1002 genera. Of 165

dicotyledonous orders 119 are represented, and of monocotyledons 25 out of 35; while the three Gymnospermæ, though nominally there, are poor in number. The proportion of vascular cryptogams to phænogams is nearly one-eighth, chiefly Ferns. Of these 52 species are not known elsewhere, a fact stamping individuality on the flora. The endemic phænogamic vegetation consists of 917 species, or a proportion of over one-fourth endemic, the dicotyledons showing one-third, the monocotyledons about one-tenth. The striking feature of the flora is the large number of endemic species and the very small number of endemic genera. The flora approximates to that of the Malayan region; but very many typical Malayan genera—those even occurring on the neighbouring island of Borneo—are wanting in the Philippines. Taking into account the dominant Australian and Austro-Malayan features, along with numerous other data and reasoning, Mr. Rolfe infers that Mr. Wallace's idea of extinction of genera by submergence will not alone explain the present peculiarities of the vegetation. Mr. Rolfe looks upon the Philippines as truly insular in the essentials of their natural history. This is not so much through their being an early separation from the Asiatic continent which has had a dip under the sea, as from their being largely of volcanic and geologically of somewhat recent origin.

SHORT NOTES ON NEW VEGETABLES.

Veitch's Perfect Gem Lettuce.—This is indeed a gem. It is the most compact Cabbage Lettuce in cultivation. We are cutting beautiful samples of it now from seed sown in a little heat in February last. From this it will be seen it is not slow in turning in, and its firm crisp heads leave nothing to be desired in a Cabbage Lettuce. As an exhibition sort it will be a favourite.

Snowdrop Potato.—Some reader of the Journal in Northamptonshire sent me a few tubers of this Potato to try two years ago, and it has been a constant success here. The first year I had tubers of it 19 ozs. in weight, plenty of them, and no disease. Last year it had several prizes in this part, and from all I can see and hear it is without doubt one of the finest of kidney Potatoes. The tubers resemble those of International; the stems and leaves those of Schoolmaster. The crop is one of the heaviest, and the quality is far above the average. It is very early too, as we dug some good dishes of it the second week in May from beds which were made up and planted in February. I consider it amongst the best for early forcing, general crop, or exhibition.

Jefferies' July Surprise Kidney Bean.—This was sent to me from Cirencester. It grows about 18 inches high, is very dark and distinct in the leaf. The pods are produced in the greatest profusion. They are narrow, long, and tender, and when forced along with half a dozen other sorts this spring it came in before any of them by eight days.

Carters' Market Favourite Spinach.—A form of the Round-seeded variety, but it is earlier than the ordinary Spinach so well known in gardens. It is also rounder and bigger in the leaf, more compact in growth, and very profitable.

Venn's Early Cabbage.—I had some plants of this sent me by parcel post last November from Mr. Oliver, Elsington Park, Alnwick. It has turned out remarkably well. It is the most compact-growing, earliest, and best of all our spring Cabbages. This season not one of the plants bolted, and every one formed a massive head of fine quality. It is very distinct, and is certainly meritorious enough to be distributed as new.

Carters' New Holborn Crimson Marble-Tipped Radish.—It is almost impossible now to get a new Radish more handsome in shape and better in quality than existing varieties, as good Radishes have become so plentiful of late, but there is still room for development and quickness in gaining maturity; and besides possessing other good qualities, this one promises to be the earliest. About a month ago I sowed six varieties of Radishes in one day, including French Breakfast and Wood's Early Frame, both well-known early sorts, but that named above was up first, and it has kept the lead ever since.—J. MUIR, Margam.

PRIMULA SIEBOLDI.

For spring decoration there are few finer plants than these, as they make effective specimens for cool-house decoration, and are very useful for cutting. There is now a comparatively large number of varieties, and the little care needed in their culture with the ease of propagation render them useful for everybody who has a frame or greenhouse.

This Primrose is rather impatient of disturbance at the roots, but as stock must be raised I advise those that intend growing them into specimens to break up the strong plants in the autumn and make two sizes of the divisions—i.e., those with strong crowns and those with small, potting the first singly in 3-inch pots, and half a dozen strong crowns in 6-inch pots, whilst of the smaller crowns a dozen can be placed in a 5 or 6-inch pot. They should be potted so that the crowns are just covered with soil. Good loam from decayed turves of medium texture, with a fifth of well-decayed manure thoroughly incorporated, and a little sharp sand, form a suitable compost. The drainage should be free, as they require abundant supplies of water when growing, and a little charcoal mixed with the soil is an advantage; or part of the drainage may be of that material with the dust sifted out. Plunge the pots in coal ashes to the rim in a cold frame, and cover the pots with cocoa-nut fibre refuse as a safeguard against

frost, and to insure uniform moisture. If the soil be moist at potting time only a gentle watering will be necessary to settle the soil about the roots, and plunged as indicated above no water will be needed until the plants commence growth. The lights should only be used to throw off heavy rains, then tilting them, and in frosty weather they may be placed on and kept close with a covering over them, whilst in mild weather the lights can be drawn off.

When the plants commence growth remove the surfacing of cocoa-nut fibre refuse, and keep on the lights, but with plenty of air whenever the air is mild. All the protection needed is to keep clear of frost. One of the essentials is that they have plenty of light and air, so as to keep the foliage leathery and the flower stems sturdy. If it be desired to accelerate the blooming, a portion of the plants may be removed and placed on shelves near the glass in a greenhouse where the temperature does not exceed 50° in the daytime from fire heat, and 5° to 10° less at night. Water will need to be given as required, never allowing the plants to want for it; and, on the other hand, it must not be given while the soil is wet. When in free growth water with weak liquid manure or soot water, which will greatly invigorate the plants, giving colour to the foliage and flowers. The plants in the frame will flower in April or early May, and can be removed to the sitting-room window or greenhouse; and along with others of a similar character, as Auriculas, &c., are charming, the smaller plants being useful for many purposes to which the larger ones cannot be applied. After flowering shift into larger pots, merely loosening the sides of the ball, but not injuring the roots, and, removing any loose soil and the drainage, transfer to others 2 inches larger in diameter, and stand on ashes in a cold frame on a north border, where they should be freely ventilated. To insure good crowns the plants must be kept cool and shady; but if the frame must stand in a position exposed to the sun it should be shaded with tiffany or some other material that will break the force of the sun's rays. Weak liquid manure may be given occasionally, and the plants will make a sturdy leaf-growth. Allowing the plants to rest after flowering, keeping dry, and standing anywhere but in a moist shady place, results in poor foliage, small crowns, and very poor flowers in spring.

In the autumn the plants must not be disturbed, but remain as they are for flowering, and they will bloom finely, as they will have the roots at the sides of the pot, which they evidently like; and after flowering again they need not be shifted, keeping them in the same pots two years, after which they should be repotted, as excessive crowding of the crowns results in a poor display of bloom.

The small crowns that were potted rather thickly may be divided the following autumn, potting the largest six in 6-inch pots, the others singly in 3-inch, by which means a stock of plants will be maintained in the most servicable sizes, and the main plants not disturbed until after the second year.

There are numbers of varieties, but many are "washy" in colour. Some of the best are grandiflora alba, lilacina, lilacina marginata, rosea alba, violacea lacinata, Ruby, Magenta Queen, Purple Queen, rosea striata, clarkiaeflora, vincæflora, and the type P. Sieboldi (cor-tusoides amoena). For cutting purposes intermedia, which is smaller than the type and magenta in colour, and intermedia alba are very pretty. These are valuable for decorative purposes and cutting.—G. ABBEY.

WHAT IS AN AMATEUR?

THIS is a question that has often been before the readers of the horticultural journals, and the present time seems to be a fitting opportunity for discussing it on its merits. The proposals placed before the readers of the Journal by Mr. J. E. Waite ought to receive some consideration. Some people seem to think that the prize lists issued by the National Auricula and Carnation Societies are drawn up from a selfish point of view. I do not think so. I believe they are made out by the Committee to meet circumstances as nearly as possible. The majority of the fanciers are *bona fide* amateurs. The champion Auricula grower (Mr. Horner) is an amateur in the true sense; but the great difficulty appears to be—and I think this is the grievance—to keep the larger growers from competing in those classes reserved for small growers. The rules of the Society provide for this, but are they adhered to? I heard it several times remarked at the exhibitions of the Carnation Society at South Kensington and Slough, that the flowers in the first-prize stands of the classes that were reserved for the small growers were not grown by the exhibitors of them, but were supplied by one of the larger growers. Is this correct? If such reports as these could be explained I am certain the Society would not lose support. It would remove the "slurs" that are made on them. I say, Let the best flowers win when staged by the real growers of them. If the same exhibitor take the prizes at each succeeding show, more to his credit. Do not make classes to keep out the best growers and so encourage bad cultivation. Let the large growers keep to themselves, and if the smaller growers feel inclined to enter the lists against them let them do so and leave the rest to exhibitors' honour.—ONWARDS.

It is of the utmost importance that when definitions in schedules of

prizes are used they should be set forth as clearly as possible. A few years ago we found it necessary to put our exhibitors at the Ealing Show into sections, so as to equalise the competitions as far as possible. We made open classes, in which the gardeners having one, two, or more men under them and the small florists could compete together. The gardeners of small places were put into a division as single-handed gardeners, meaning thereby one who has no constant assistance, though he may have occasional help. The amateurs were put into a division, the term "amateur" being defined as one who does not constantly employ a gardener, but who has occasional help in his garden. Then we have a fourth division, in which cottage and allotment gardeners compete together. We find this arrangement to work uncommonly well on the whole, and I commend it to the attention of managers of flower shows. I send you the foregoing remarks as a contribution to a discussion now going on in your columns.—R. DEAN, *Hon. Sec. Ealing, Acton, and Hanwell Horticultural Society.*

EXTRA EARLY MILAN TURNIP.

THIS is a new introduction highly recommended by Messrs. Veitch, and having, moreover, the impress of excellence in the reliable form of a first-class certificate from the Royal Horticultural Society. Two seasons' trial had placed Early Munich indisputably at the head of all the early Turnips of which I could get seed. The best test, therefore, of Extra Early Milan was to sow it alongside of Early Munich. I have done so, and find it quite a week earlier than Early Munich, and flesh of excellent quality, white, sweet, crisp, and tender. At present there is no indication of premature bolting to seed, and I have every reason to regard it as a decided acquisition, superior to all other early varieties, and highly worthy of general culture.

Not only for its intrinsic merit do I call particular attention to this new Turnip, but also because advice was recently given to readers of the Journal to sow either it or Early Munich on the same day to obtain a supply of roots twelve days before other sorts are ready. Now, it is certain that Early Munich is surpassed for first place, and it may prove a bad second if, as Messrs. Veitch assert, Early Milan retains its good qualities and remains a long time fit for use, while Early Munich soon gets hot and bitter. The best sorts to follow Early Milan, therefore, are Early Red American Strap-leaf and Early Strap-leaf White Stone, followed by Snowball, Veitch's Red Globe, and Chirk Castle.—EDWARD LUCKHURST.

CULTURE OF THE AMARYLLIS.

It is quite certain that the Amaryllis will become a popular plant. Those who have not been able to visit the nurseries of Messrs. Veitch at Chelsea, or of Mr. B. S. Williams at Holloway, whilst the Amaryllis season is at its height can form no conception of the effect produced by these gorgeous plants. The varieties that have been raised at both establishments during late years are far in advance of those we were familiar with a few years back. The only deterrent fact to many would-be growers is the high price of the bulbs, which is owing to the slow increase of the majority, consequently the price will generally be high unless a variety may be perpetuated by seed in quantity. The seedlings as a rule bloom the third year if they have received generous culture. Those who are not in a position to procure a collection of the Amaryllis should try to have a few of the best of each type, and endeavour to raise seedlings. The culture of the Amaryllis is not difficult, but they require careful attention. Some gardeners a few years back (and there may be some now) maintained that to have the Amaryllis in good condition that the bulbs ought not to be dried off, but have moisture sufficient to keep the foliage green. These views are quite exploded, unless they can produce better examples of culture than those grown by the above-mentioned firms.

To produce good Amaryllises careful attention is required after blooming. The best position for them whilst making their growth is a span-roof house, with a bed in the centre for holding tan, and a walk round, or a bed on each side with a walk in the centre. The beds should be well filled with tan to keep the bulbs well up to the light; if the tan is low down in the pit the plants do not receive sufficient air. If it is new tan some old worn-out tan should be mixed with it to prevent violent heating, as a gentle bottom heat is what they require. Blinds should be provided to guard against bright sunshine.

Potting the Bulbs.—The first batch should be potted early in February. The soil best adapted for the Amaryllis is six parts fibry loam, one part prepared horse manure, with a half part of peat, with sufficient sand and pounded charcoal to keep the soil open. The size of pots used should be according to the size of the bulbs. They should also be well drained, the old soil being removed, and pot very firmly. They should then be plunged in the tan.

Watering.—No water should be applied to the soil until the bulbs have started into growth, and then it must be applied carefully. It must be remembered that when a plant is plunged, although the soil may look dry on the surface it may not be so underneath. If the house is kept well damped they will not dry very much. As the

season advances and the plants are growing well a slight syringing will be beneficial at closing time. A night temperature of 50° will do to start the bulbs, advancing to 55° as they increase in growth, allowing 5° extra by day with fire heat. A few days before the blooms are fully expanded the plants should be taken out of the tan bed and placed on the surface—that is, if the plants are required for the conservatory, but when there they must not be placed in a draught. After they have finished blooming remove them to the growing house, give the tan a turn, and plunge them again. The plants will then commence their second growth. Syringe in the afternoons of fine days, and give a good general watering about once a week. By the commencement of October the heat in the bed will have vanished, or if it has been kept up by hot-water pipes turn it off. The plants will be preparing for their winter rest; no water should be applied either at the roots or in the atmosphere, and ventilate freely. As the foliage dies winter the plants in a cool house free from frost if the house they have been grown in is required for other plants; if not, allow them to remain there.—A GROWER.

THE VINEYARDS OF OLD LONDON.

WE may supplement the observations recently published upon vineyards in England by some remarks upon the London vineyards more particularly, as being of interest to many readers who are in the radius of the million-peopled metropolis. Since this was the centre, undoubtedly, from which the knowledge and practice of horticulture radiated throughout our islands, it is not surprising that we have early records of the cultivation of the Vine in and near London. The place evidently once well suited the plant. There were plenty of gentle declivities, well watered, and to a considerable extent sheltered from keen winds by the old woods and forests that have now vanished, also an abundance of rich manure was attainable. Some say the climate of London was more favourable to the Vine formerly than it is at present, but much difference of opinion prevails on this point; the fact, however, is indisputable that the Vine was grown freely, and yielded well usually. It is evident there were vineyards about London in Saxon times (and possibly earlier), for Domesday Book records one at Holborn that belonged to the king, the after history of which is doubtful. Vine Street, Saffron Hill, was not named from it, but from the vineyard of Ely Garden, which dates from a later period. Also that memorable volume states that in the village of Westminster were four "arpents" of vineyard, held from St. Peter's by one Bainard, and at Chenesiton—i.e., Kensington, three "arpents," for which De Vere did service. Of the latter vineyard no trace remains. The former is very exactly described in documents of the Stuart times. It was "within the Millditch," the site somewhere near St. John's church and a Vine Street which still exists in Westminster. The Royal vineyard on the slopes above the "Old Bourne" may have subsequently become part of the botanist Gerard's garden, or that of one of his friends in that locality, one famous for horticulture during the reign of Elizabeth, though so different now. The vineyard of Ely Place was attached to the town house of the Bishops of Ely, and was planted by John de Hotham in the fourteenth century. It was part of the property which Queen Elizabeth forced Bishop Cox to surrender to the Crown in order that she might confer it upon her favourite Sir Christopher Hatton. Beside the reminiscence of Vine Street, the name of Saffron Hill close by recalls the time when Saffron was freely grown hereabout.

The unpromising but gradually improving Drury Lane of our day was once a real lane winding through the village of St. Giles's, having here and there a noble's or citizen's house, surrounded by a spacious garden. Few who live near, or who pass Vinegar Yard, a turning out of the above lane, are aware that its name is a corruption of Vine Garden Yard from a vineyard on the spot during the middle ages, but the Vines, or most of them, had been removed by the reign of Charles I. When we cross the Thames into Surrey we find a Vine Street in Lambeth, which the local historian says (on the information of the oldest inhabitants) was so called from vineyards that formerly flourished in the neighbourhood, upon which he adds the comment that probably the Londoners grew Vines more for shade or ornament than with the view of getting Grapes, but we should rather judge they got a sufficient return in fruit to encourage their culture. We wonder how the Londoners guarded their Grapes from juvenile depredators in the olden times. Certainly the laws against stealing were very severe until the seventeenth century. It is noteworthy that Lambeth and the adjacent Vauxhall more recently yielded quantities of Grapes for the market; these were, however, raised under glass, and the nurseries have given place to streets of houses. Attempts have been made of late to promote the planting of Vines about the south London suburbs; the result remains to be seen.

At Hammersmith a nursery, founded by James Lee, botanist and gardener, yet has the appellation of the "Vineyard Nursery." For some years in the early part of the reign of George III. much Bur-

gundy wine was produced here, and the wine was retailed on the premises. To add one more fact, the famous nursery of Brompton Park had a long extent of old wall, which had been in the years it was attached to a mansion a portion of the boundary that enclosed the deer park. Vines were planted along this wall, which extended nearly half a mile, about 1760, and, being yearly propagated, young plants were sent to various places in this country, or even abroad, and much fruit was obtained in favourable seasons.—J. R. S. C.

HARDY AZALEAS.

MUCH is written about hardy shrubs, and some of them really deserve all that can be said in their favour; but there are many which have no merit, and their introduction would only end in disappointment. Prominent amongst shrubs of the highest decorative value we would unhesitatingly place hardy Azaleas. It is really astonishing these splendid plants and flowers are not more noticed. They deserve to be strongly recommended to planters; it is impossible to say too much in their favour. In April, May, and June the gorgeous display they make in the pleasure grounds defies description. The flowers are pretty in form, beautiful in colour, and pleasing in fragrance; they develop in the utmost profusion, remain a long time in bloom. Of late our bushes of pink, yellow, white, crimson, and all shades have been charming. The largest are 10 feet high and from 30 to 40 feet round, and when these huge masses are in full beauty they are most impressive.

Rhododendrons are undoubtedly showy, and many consider them glaring, but they cannot outshine the hardy Azaleas in colours and fragrant flowers. No shrub I have ever seen in the pleasure grounds could surpass them, and I would advise all who have a shrub bed or border set about the introduction of some of these, and where space will admit a general collection may be obtained with certainty of their giving the utmost satisfaction.

There are scores of varieties, but I will only name a dozen of the most distinct and beautiful:—Admiral Ruyter, red, spotted with orange; Ardentissima, deep vermillion; Beauty of Flanders, sulphur; coccinea grandiflora, dark crimson; Cuprea Ardens, brilliant scarlet; Etcharis, deep pink; Globosa alba, pure white; Nathalie, fine rose; Or on, white, shaded with pink; Quadricolor, orange, red, salmon, and green (curious); Subtillissima, straw colour; Victor, crimson.

These are all distinct and beautiful, and form a very charming group. As to situations for them, they may be introduced to all kinds of shrub beds and borders, and in small clumps on the grass they have a good appearance. The spring is the best time to buy them in and plant out; but when they can be had in pots, as they may be in some nurseries, they may be planted now or at any time. A sandy soil deep and cool, composed of half peat and half loam suits them admirably, especially to induce them into immediate and free growth at the first; but when established the roots will run into almost any soil, and many of our best plants are now growing in soil which has no trace of peat. When planted at first, and until the roots are active, water should be given liberally at the roots in dry weather; but when established and growing they require no more attention than the most common Rhododendrons.—M. M.

CACTACEOUS PLANTS.

CONTINUING the notes on the columnar Cereus from page 405, the following are worthy of attention:—

CEREUS GIGANTEUS, *Engelmann*.—No stranger phase of vegetation can be conceived than that formed by the Giant Cereus in the districts of Mexico where it abounds, for these enormous columns of vegetable matter have been recorded as attaining the height of 60 feet, and specimens 40 to 50 feet high are of frequent occurrence. In particular localities, too, they are exceedingly numerous and near together, views of the scenery in such districts having a most peculiar appearance. Travellers have without exception commented in wondering terms upon these singular occupants of rocky or sterile soil; but one of the best descriptions is that by Möllhausen in his "Diary of a Journey from the Mississippi to the Coasts of the Pacific," in which he remarks: "The absence of every other vegetation enabled us to distinguish these Cacti columns from a great distance, as they stood symmetrically arranged on the heights and declivities of the mountains, to which they imparted a most peculiar aspect. Wonderful as each plant is, when regarded singly, as a grand specimen of vegetable life, these solemn silent forms, which stand motionless even in a hurricane, give a somewhat dreary character to the landscape. Some look like petrified giants stretching out their arms in speechless pain, and others stand like lonely sentinels keeping their dreary watch on the edge of precipices." In Dr Engelmann's magnificent work on the Cactaceae of the Boundary Survey is an admirable engraving of such a scene on the banks of the Gila, New Mexico, from a drawing by Möllhausen; and so well does this portray the characters that it has been reproduced in several works (including the *Flore des*

Serres, vol. xv., and the *Treasury of Botany*). Some of the giants are shown with enormous stems, from which proceed a number of branches, which, when a short distance from the main stem, assume a rigidly perpendicular position, and give a candelabra-like appearance to the plant. One is represented with eight branches, varying in size, while older specimens which have lost the greater portion of the soft cellular tissue have only the woody or fibrous matter remaining, and this has been most strangely torn, until the ends of the branches resemble birch brooms. In this state they remain for many years, still further increasing the peculiarities of the landscape.

Julius Froebel has given a very graphic description of a *Cereus* district in his "Travels in Central America," page 498, which is worth reproduction here: "In the lower part of the valley of Santa Cruz the gigantic columnar Cactus, *Cereus giganteus*, is first seen upon the road. The inhabitants of the country call it Saguaro; but various authors, and recently Bartlett, have applied the name of Pitaya (Pita-haya) to this remarkable plant. This name, however, belongs to another species of Cactus of a similar but much lower growth. The Saguaro presents a thick fluted column, the size of a man's body, and 30, 40, and even 50 feet high, with sometimes three or four branches at its top, the whole looking like a gigantic candelabrum. The fig-shaped edible fruit grows at the edge on the top of the columns; and from the great height of the latter it would be difficult to get at them, did not this remarkable plant itself afford the means of reaching it. The old stems, when decayed, split into a number of thin poles, standing in a circle the height of the entire column, enveloped in a loose network; and by the aid of these the traveller is enabled to knock down the fruit. I have been told that these poles form an article of export from the port of Guaymas, and in Europe are made into walking sticks, and sold under the name of "Spanish canes." I cannot, however, vouch for the correctness of this account. The Pimas at the old Mission of San Xavier del Bac had a large store of Saguaro fruit, which is used as food in various ways. It is eaten fresh; the sap is boiled to a syrup, known throughout Sonora by the name of 'Miel de Saguaro'; and a flour is prepared of the cleaned and dried seeds, which have some resemblance in appearance and taste to Poppy seeds, and are contained in the fruit in great quantities. This flour is made partly into bread and partly into a chocolate-like drink, called Atole. The fruit of the Pitaya is said to be far better than that of the Saguaro. Both are of great importance to the population of Sonora. In some bad harvests occasioned by the want of rain, shortly before my journey through this State, a large portion of the inhabitants were obliged to live on these and other wild Cactus fruits."

Cultivated plants of this *Cereus* are mostly of small size, not exceeding 4 or 5 feet in height, and the majority are much smaller. These are generally inclined to be globular when young, but as they advance the ridges become apparent, of which there are generally twelve, 1 inch deep and thick, and $1\frac{1}{2}$ to 2 inches apart. The spines are ashy grey, twelve to twenty or more in a cluster, rigid, half to 1 inch long, the clusters being about half an inch apart. The stem is 6 inches to 12 inches in diameter in cultivated plants, but becomes much larger in its native habitat. The flowers I have not seen in England, but they are described by Engelmann as creamy white, the petals $1\frac{1}{2}$ inch long and three-quarters of an inch broad. By the same authority it is said that the fruit has the hardness of a green Cucumber, bursting open with three valves, and then looks like a flower, owing to the abundant crimson pulp inside with black seeds. This pulp, which has the consistency of a fresh Fig, separates from the other portion of the fruit when ripe and falls to the ground.

Some difficulty is experienced in growing *C. giganteus* in this country, its progress being very slow in its early stages, and in reference to this it is worthy of remark that Engelmann mentions "the young plants are almost always found under the protecting shade of some shrub, especially *Ceradium floridanum*, so characteristic of the barren wilderness." It would therefore appear that shade is beneficial in assisting the growth at first, and the hint might prove serviceable to growers who are not very successful with it. The seeds germinate freely, and those distributed by Mr. Thurber in Europe and America some years ago have yielded a large number of plants, so that the species is by no means rare. Closely related to this is *C. Thurberi*, which is found in some districts of Mexico, and is said to bear a fruit like an Orange, 3 inches in diameter, with crimson pulp. It is termed Pitahaya by the natives, and under that name is mentioned by several travellers.

Many more species might be described, but it will suffice to mention a few of the most interesting, as large collections are seldom seen in cultivation. *C. niger* is noteworthy for its peculiar dark green colour, which is especially observable in the young growth. *C. Jamacaru*, a Brazilian species, is very distinct and even handsome, for the ridges are very prominent, and the colour of the young shoots is quite a glaucous blue, sometimes very bright. *C. Tweediei* is a pretty and distinct species, with slender stems and tubular orange-yellow flowers, 2 inches long, and crimson stamens. It is free, and when in flower is very beautiful. *C. triangularis* is an old inhabitant of English gardens, and is easily distinguished by its triangular stems, and is remarkable for its bright scarlet fruit, the size of a goose's egg, the flavour of which is compared to Strawberries; indeed the plant has been called the Strawberry Pear. *C. repandus* also has a fruit which is considered to resemble a Strawberry in flavour, and the dry stems were at one time used as torches to assist the natives in catching fish. *C. macrogonus* is a quick-growing species, and is therefore useful for grafting many other Cactæe upon, as has been already noted. *C. eandicans* is notable for its slow growth, and as far as I can ascertain it has never flowered in this country.

Mr. Major has a plant in his collection at Cromwell House which is nearly thirty years old, and is not 2 feet high, one of the most extraordinary instances of slow growth which has come under my observation.

The climbing or slender-growing species, which include some of the most beautiful and useful of the *Cereus* in a horticultural point of view, are numerous, but the following may be named as particularly worthy of culture:—

C. GRANDIFLORUS, Haworth.—The Night-flowering *Cereus* has gained a fame which entitles it to prominent notice, and plants might well be included in every garden, for its flowering is a source of interest to the least observant persons. In the character of producing its blooms at night it is not alone, as several of the slender-growing species have a similar habit, but none equal this in beauty and fragrance.

"That flower, supreme in loveliness and pure
As the pale Cynthia's beams, through which unveiled
It blooms, as if unwilling to endure
The gaze by which such beauties are assailed."

The flowers are really magnificent, and a plant with a dozen or two

Fig. 96.—*Cereus grandiflorus*.

expanded at the same time has a superb appearance, particularly in the early evening when the flowers first expand, and the powerful fragrance they emit is very agreeable, having been not inaptly compared to Vanilla. The stem is nearly cylindrical, with a few faintly marked ridges, bearing small clusters of spines, and rarely exceeds 1 inch in diameter, but attains a length of many feet, freely branching. The flowers vary in size from 6 inches to 12 inches in diameter, the usual size being 8 or 9 inches; the sepals are narrow, acute, and spreading, about one-quarter of an inch broad, 4 to 5 inches long, and thirty to forty in number, forming a beautiful fringe round the broader pure white petals, which are more in the form of a cup, the stamens being extremely numerous with very long filaments. Mr. Major, however, informs me that he has seen two very distinct forms, one having the petals distinctly cupped, and the other with

them spreading more like the sepals, the two forms also differing slightly in colour.

Large specimens of this *Cereus* are not rare in old gardens, but the finest known to me is one in a stove at Leigham Court, Streatham, the residence of Mrs. Treadwell. This covers a space on the back wall about 30 feet long and 3 or 4 feet wide. The old stem and roots are lost, the plant subsisting entirely upon the moisture in the atmosphere of the house and that furnished by the moss with which the trellis is packed, and in which the branches have freely rooted. About forty grand flowers have been produced by this plant in one season, which generally expand in batches of a dozen or so, and the only encouragement the plant receives when making its growth is syringing it with clear water and occasionally with very weak liquid manure. Flowers were kindly sent me by the gardener, Mr. E. Butts, and the characters are well portrayed in the woodcut (fig. 96). Another very large specimen is grown in a house at Pendyffryn in Wales, which Mr. Siddall of Chester informs me has had from sixty to eighty flowers open at one time.—LEWIS CASTLE.

(To be continued.)

A ROSE'S REPLY.

REALLY, Mr. Editor, I wonder you insert such antiquated sentiment as on page 400. Dear old indignant dowager! or, I wonder, was she a maiden blush in her best days, and has been blushing for the blindness of the men ever since? What, not want to be exhibited? Is there a woman in the world—a Rose I mean—that objects to be looked at properly, front row or back row?

Better fourteen days of D'Ombra
Than a cycle of Cathay.

And then the name will not do—Pedigree Roses! Perhaps dear Mr. Bennett, had he taken as much pains over that as over our appearances' might have found out a prettier one. There are plenty across the water which it takes two pens to write. Handsome is that handsome does. I always feel much obliged to the featherless bipeds that slave for us, and look us out husbands with such care, and put us in such pretty boxes, and carry us to Crystal Palaces and bow down before us. What could the creatures do more? I think it was a Wallflower, not an old Rose, who wrote to you. Country quarters are all very well; pretty parsonages may do for good old Cabbage, Persian Yellows, and common Mosses, but give me the glorious thrill of battle and the gathering of the clans,

"And that stern joy which warriors feel
At foemen worthy of their steel."

"Vulgarised," quotha. The slaves that toil for us, and fetch and carry, are refined by their very employment. Scentless Dahlias, flaunting Hollyhocks, preposterous Pæonies, might perhaps be called such. I cannot say I care much for those pretty impostors, those Orchids, that now all the world is going mad on. But Roses vulgarised! Rose shows reprehensible! Our lovers deserting us! This season will show.

"Were I a flower knight in arms,
As one day I may be,
My heart should own no meaner charms:
A show Rose still for me.

"'Tis hers the crowded tents to brave
That thinner petals fear,
To challenge east, and west, and north,
In size or form come near.
She can the serried ranks opposed,
With eye unflinching see;
Emerge victorious from the strife,
With medals gold and silver rife:
A show Rose still for me."

—A ROSE OF THE PERIOD.

TUBER-BEARING SOLANUMS.

ON January 17th of the present year Mr. J. G. Baker of the Kew Herbarium gave the outline of a paper upon this subject before the Linnean Society, a summary of which we gave upon 57 of this Journal (January 24th). Mr. Baker's observations and descriptions of the species have been printed in the Society's journal, and are now issued separately. Full descriptions of the species are given under the countries in which they are found, together with general remarks as to the climates and positions in which they abound. Plates are also given of the principal types—*Solanum tuberosum*, *S. Maglia*, *S. cardiophyllum*, *S. Commersoni*, *S. Jamesii*, and *S. oxycarpum*, which Mr. Baker considers entitled to be regarded as species in a broad sense, the remaining fourteen so-called species being probably varieties of *S. tuberosum* or *S. Commersoni*.

The paper concludes with some interesting economic suggestions which we here reproduce.

"What Lord Cathcart asked for were any suggestions that a botanist might be able to give, founded upon his knowledge of the Potato plant and its geographical distribution, that were likely to be of practical value to cultivators. In reviewing the subject the considerations of this character that occur to me are these:—

"In the first place, it always seems to me that cultivators work upon the tacit assumption, if I may so express it, that the one object in life of the Potato plant is to grow Potatoes, and that this assumption has no sound foundation in fact or reality. *Solanum* is one of the largest genera in the vegetable kingdom. About 900 names stand in the botanical books

as species, and Bentham and Hooker estimate that probably 700 of these are really distinct. Of these 700 it is only six that grow Potatoes at all, and the remainder all maintain their hold in the world as most plants do, by means of their flowers, fruits, and seeds. I do not think that the Chilean *S. etuberosum* and Mexican *S. snaveolens* are more than mere forms of *S. tuberosum*, and they are said to be quite destitute of tubers; and there is the fact noted by Sir J. D. Hooker, that when *S. Maglia* was first grown at Kew, for two years it did not yield any tubers. A great many of the cultivated varieties rarely produce flower and fruit. Any plant brought to the tuber-bearing state is in a disorganised unhealthy condition, a fitting subject for the attacks of fungi and aphides. The great difficulty with which we have to contend in fighting disease is that in the Potato, as in other cultivated species, we grow in great masses plants which in a state of nature are scattered amongst others.

"The relationship of tuber to fruit is so clearly shown by one of the experiments of Mr. T. A. Knight that I will cite it in this connection. 'Every gardener knows' (he writes in 'Philosophical Transactions,' 1806, p. 297) 'that early varieties of the Potato never afford either blossoms or seeds; and I attribute this peculiarity to privation of nutriment, owing to the tubers being formed preternaturally early, and thence drawing off that portion of the true sap which, in the ordinary course of nature, is employed in the formation and nutrition of blossoms and seeds. I, therefore, in the last spring planted some cuttings of a very early variety of the Potato which had never been known to bloom in garden pots, having heaped the mould as high as I could above the level of the pot, and planted the portion of the root nearly at the top of it. When the plants had grown a few inches high they were secured to long sticks, which had been fixed erect in the pot for that purpose, and the mould was then washed away from their stems by a strong current of water. Each plant was now suspended in the air, and had no communication with the soil in the pots, except by its fibrous roots; and as these are perfectly distinct organs from the runners that generate and feed the tubers, I could readily prevent the formation of them. Efforts were soon made by every plant to generate runners and tubers, but these were destroyed as soon as they became perceptible. An increased luxuriance of growth now became visible in every plant, numerous blossoms were emitted, and every blossom afforded fruit.'

"Secondly, a suggestion as to what might be done towards widening the power of climatic adaptation of the cultivated Potato. There are certainly six distinct species of tuber-yielding *Solanum*, each with its own distinctive climatic peculiarities. I went to Messrs. Sutton's trial grounds specially to investigate this point, and came away fully satisfied that all the numerous varieties in cultivation had originated from *S. tuberosum*, as here defined. As far as climate is concerned, it cannot be doubted that *Solanum Maglia* (or the Darwin Potato as we might suitably christen it in English) would be better fitted to succeed in England and Ireland than *S. tuberosum*, a plant of a comparatively dry climate. We have indisputable testimony that *S. Maglia* and *S. Commersoni* yield readily an abundant supply of eatable Potatoes. What I should suggest is, that these should be brought into the economic arena, and thoroughly tested as regards their economic value, both as distinct types and when hybridised with the innumerable *tuberosum* forms."

A RAMBLE IN DERBYSHIRE.

IMAGINATION cannot form a view of more luxuriant rural beauty than that seen as the visitor wanders by the banks of the river Derwent from Cromford station, near Matlock, to the isolated village of Holloway, where amongst the hills industry is rife with spinning and weaving. Entering the village on the right we are at once struck with the residence of Wm. Walker, Esq., Lea Wood, a splendid piece of architecture in the old half-timbered style, erected about six years. It is approached by a straight wide drive through a fine dark oak gate with a commodious lodge, quite in harmony with the mansion. On each side of the drive is a broad band of turf, having a raised bank on the left of fine ornamental and flowering shrubs, hiding the kitchen garden, vineries, and plant houses. A broad walk surrounds the mansion, looking down on one side to a very pretty flower garden, with the valley of the Derwent below, and the fine woods of Alderwasley in the distance. The spring bedding just fading displayed fine taste in the blending of soft colours—a centre bed composed of Wallflower, *Arabis alba*, *Cheiranthus*, *Forget-me-not*, white Daisy, with Royal Standard and Duc Van Thol Tulips intermixed was a lovely combination. On another side of the mansion the grounds rise to some extent with terraces, adjoining the estate of Miss Florence Nightingale, a well-known heroine. A pretty slope on this side of *Berberis* pegged down was very effective, with the conservatory gay with Roses fine, &c., in a snug corner, completed a very harmonious and compact dressed garden. Grapes were in excellent condition, with fine crops of Muscats, the plant houses being well stocked with good plants in excellent condition. A very fine specimen of *Adiantum farleyense* grown close to the glass was telling. The whole keeping reflects great credit on the able and intelligent gardener, Mr. Alfred Anderson.

Passing a little higher on the opposite side of the road are seen the glass houses of a gentleman who evidently is a great lover and enthusiastic grower of fine plants. The houses abound with good things in fine health, telling what R. Wildgoose, Esq., enjoys, and his clever plant grower, Mr. C. Yates, can produce for so worthy a master. The old *Sparmannia africana* was very striking and pretty in the conservatory, with other good plants in large numbers. Houses are being built, and there is great promise of this becoming a fine plant-growing place. Mr.

Yates seems gifted in this way, and he receives every encouragement from his employer.—GEORGE BOLAS.

PEONIES.

WHAT is finer than the great saucer-like flowers of the single and the large globes of the double varieties of *Pæony*? No plant can vie with them in their season for affording a show in the borders. I do not mean to put forward the *Pæonies* as rivals of the *Iris* or *Pyrethrum*, for the herbaceous border is large enough to hold the three, and such a trio cannot be equalled in late May and early June for beauty and usefulness. The *Pæony* is an old-fashioned plant; it could be found in almost every garden many years ago, and is coming to the fore again. Pliny mentions the *Pæony*, stating it was so named in compliment to *Pæon*, a famous physician of antiquity, and it (*Pæonia officinalis*) has been in England since 1560, and of the family we claim one—viz., *P. corallina*. Gerard mentions having seen it wild at Southfleet in Kent. How they come to be termed Chinese *Pæonies* I cannot imagine, as China contributed only some forms of the species *albiflora*, the chief of the species being European. There is no doubt we are indebted to *P. albiflora fragrans* for the scent which many of the French varieties possess, otherwise the Celestials have a very small claim to the origin of the herbaceous *Pæony*.

These flowers travel well, and are useful for cutting, some of them being delightfully fragrant. Some consider them coarse and lumpy; but they are not a whit more lumpy than a *Rose*; indeed they are to the herbaceous border, shrubbery, and wild garden in May and early June what the *Rose* is later on. Call them May *Roses* if you will, or Mountain *Roses*, as I believe the Spaniards do, only do not class them with anything less than their merit deserves, which is as a foremost decorative and useful plant and flower in early summer is especially valuable. What are finer for large vases than bright massive blooms of *Pæonies* set with long stems supporting the flowers amid their handsome foliage? In a cut state they last a long time, and being the hardiest of hardy plants, they are not so soon dried up as more tender plants. One of the great merits of these *Pæonies* is their size and glowing colours, and they can be grown by everybody, not being very fastidious as to soil if it be rich, porous, and deep, and that any soil can be made by trenching and adding manure; lightening heavy soils by adding ashes or the refuse from the potting bench suits them exactly. They like moisture, only it must not be stagnant, and when in flower water will help them wonderfully to swell the second flowers, the first being always the largest, and the side ones smaller. After flowering the application of liquid manure will help them to form strong flower buds for another year, and a mulching of short manure in autumn is advantageous, as it is in a light shallow soil in summer.

Once planted they take care of themselves; but until they become established no estimate can be formed of their capability for effect. They should be planted in autumn, that being the best time to divide them; every crown taken off with a portion of tuber will grow, and they must not be planted deeply—merely covering the crown. If planted in spring they do not succeed nearly so well as when planted in autumn. Numbers of varieties, both single and double, are described in catalogues.—G. A.

AT the General Meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday, G. T. Clark, Esq., in the chair, the following candidates were unanimously elected Fellows—viz., Edward C. Browning, Walter Barnard Byles, Dowager Viscountess Canterbury, Stewart Clark M.P., Mrs. Stewart Clark, Harbhamji Kumar of Morbi (India), Mrs. G. Head, J. Mears, Edwin Roper, M.D., Henry W. Tugwell, and Maj. r Williams.

— ESTABLISHING A ROOKERY.—We are reminded that this topic was discussed some years ago in "Science Gossip," and several naturalists expressed opinions; the conclusion then was that there is no means known of inducing rooks to found a colony, they will do as they please.

— THE CANTERBURY GARDENERS' MUTUAL IMPROVEMENT SOCIETY announce their seventh autumn Show for November 14th and 15th, when prizes, chiefly of small amount, will be offered in very numerous classes for *Chrysanthemums*, fruit, and vegetables.

— WE learn with pleasure that the Lady Mayoress has kindly consented to hold "A ROSE SHOW AND FLORAL FETE" AT THE MANSION HOUSE, on July 17th, in aid of the funds of the Royal Hospital for Children and Women, Waterloo Bridge Road, London, S.E., of which Mr. R. G. Kestin is the Secretary.

— "CASUALTIES AND DISEASES OF VEGETABLE LIFE."—Under this title, Mr. Bruce Findlay, Curator of the Royal Botanical and Horticultural Society of Manchester, delivered an interesting lecture in the Town Hall, Manchester, early in the present year, which is now issued by Mr. John Heywood in pamphlet form. The subject is divided into three sections—1, Wounds, under which are considered boring, fractures, pruning, felling, destruction of buds and leaves; 2, Diseases, including blight, smut, mildew, honeydew, flux of juices, gangrene, suffocation, and consumption; and 3, natural decay.

— THE VALE OF EVESHAM HORTICULTURAL SOCIETY will hold an Exhibition of *Roses* on July 8th of the present year in the Workman Pleasure Grounds in conjunction with the annual regatta. The classes are comparatively few, only fourteen being enumerated, but the prizes are liberal. Messrs. Cranston & Co., Hereford, offer three prizes for a basket of *Roses* arranged with *Rose* foliage only, and F. D. Dixon-Hartland, Esq., M.P., also offers prizes for *Rose* bouquets and button-holes.

— "J. W. S." writes:—"At the residence of H. E. Watson, Esq., Shirecliffe Hall, Sheffield, there is now a very fine specimen of the beautiful RHODODENDRON DALHOUSIÆ in full bloom, with between sixty and seventy of its large yellowish-white flowers, which give a very agreeable odour during the evening and through the night. This species will grow to a great size with very little soil, as the plant referred to is about 10 feet high; its roots are confined to a 14-inch pot, and it is in vigorous health, associated with the *Camellias* in the *Camellia* house. The very fine examples of the latter have, under the skilful management of the gardener, Mr. Udale, justly gained the reputation of being some of the best in the country."

— MR. G. BOLAS, Hopton Hall Gardens, Wirksworth, Derby, sends us flowers of CEANOTHUS VEITCHIANUS, and remarks that it is "a most charming effective plant on the wall. It was planted five years ago from a small pot, and now covers a space 20 feet by 12 feet. The flowers kept peeping all winter, and last year it was equally as good. On a wall 120 yards long, covered with good shrubs and climbers, nothing surpasses this."

— A CORRESPONDENT writes:—"Your leading article on DOUBLE PELARGONIUMS (page 397) cannot fail to be instructive, and came just right in the season, so that stocks can be renewed. I do not grow many, but have one in bloom—namely, Pretender, and I would like to hear if this is likely to be a suitable variety for pot culture. I like its present appearance. Madame A. Baltet is good; the same can be said of M. Thibaut, but Asa Grey became spotted in the leaf, though the colour of flower is novel."

— AT the annual Show of the BATH AND WEST OF ENGLAND SOCIETY, which opens at Maidstone on June the 2nd, and continues for five days, the horticultural tent will contain a choice display of exotic plants and flowers, the opportunity of exhibiting rare specimens having been largely taken advantage of. The plants will be arranged with a special view to illustrate the beautiful effects which can be obtained by skilful groupings and combinations of colour under the superintendence of the Hon. and Rev. J. T. Boscawen, who has worked so indefatigably and successfully at the Exhibitions of the Society for a number of years.

— HOVEA CELSII.—Mr. C. M. Major of Croydon writes:—"Your correspondent 'Conservative Rose' asks for the names of plants with blue flowers. Many have been given, but one that I have always esteemed as the most beautiful has been forgotten. I mean *Hovea Celsii*." This is undoubtedly one of the most richly coloured of blue-flowered greenhouse plants, and one of the good old plants that are too much neglected.

— ALEYRODES VAPORARIORUM.—A correspondent writes:—"These tiny insects are certainly difficult to kill, and some say that, as

with the red spider, nothing is so effective as sulphur applied as vapour in houses or combined with water out of doors and thrown in by a syringe. Another species is frequent upon the Cabbage, and I have observed that a solution of softsoap 'fetches them;' they cannot stand this. Also I think it probable either hellebore tea or diluted paraffin would kill." Mr. William Jenkins thinks that fumigating three or four times in succession will eradicate the pest. Mr. Stephen Castle observes, after trying fumigation and various insecticides, he has to confess himself beaten by this insect. The only method of eradication he can suggest as likely to be effectual is cutting down the affected parts of Tomatoes that it infests, lay them on the border, and the next morning carefully take them out of the house and burn them.

— A CORRESPONDENT, in referring to the admitted beauty of Horse Chestnuts when in flower, states that "the LARGE CHESTNUT AT MONCREIFFE (said to be the largest specimen in the country) presents just now (May 26th) a noble appearance, and is well worthy of admiration. This colossal giant from its topmost branches down to the great limbs which sweep the ground is one complete mass of dark healthy foliage, and from nearly every growth is produced a spikelet of white blossoms standing out bold and erect. Its huge size and majestic appearance truly constitute this the finest tree of its class in the neighbourhood."

— THE following RECIPE FOR DESTROYING RED SPIDER AND MILDEW has been sent to us by an experienced gardener who has proved the value of the preparation:—"2 lbs. yellow sulphur, 2 lbs. lumps of lime; boil it twenty minutes in 10 quarts of water, keep it well stirred when boiling, let it stand till cold, then bottle and cork down; put one wineglassful to an ordinary size pail of water." The best time is to syringe in the evening, and in a day or two the plants, &c., may be syringed with clean water. One dressing is generally sufficient, but should be repeated if required.

— THE annual Show of the CHISWICK, TURNHAM GREEN, AND DISTRICT HORTICULTURAL SOCIETY will be held in the Royal Horticultural Society's Gardens on Thursday, July 3rd. Substantial prizes are offered in the fifty-seven classes for plants, cut flowers, fruit, and vegetables, and we doubt not that the high character and diversity of the Society's Shows will be maintained. Mr. J. T. Musgrave, Branstone Lodge, Heathfield Gardens, Chiswick, is the Honorary Secretary of the Society, and from whom schedules are procurable.

— IN the remarks referring to the new ROSE HER MAJESTY on page 378, the impression is conveyed that Mr. Bennett does not intend distributing this variety in England. There is no foundation whatever for this opinion, and it is possible that the writer had some confused remembrance of the agreement relating to the variety William Francis Bennett, which was sold provisionally to an American firm.

— EALING, ACTON, AND HANWELL HORTICULTURAL SOCIETY. — On the 27th inst. a large body of members of the above Society entertained at dinner their President, the Right Hon. S. H. Walpole, in commemoration of the fact that the present year is the twentieth anniversary of Mr. Walpole filling that position. E. M. Nelson, Esq., J.P., of Hanger Hill House, occupied the chair, among the company being the Right Hon. Lord George Hamilton, M.P., the Rev. G. Henslow, &c. The toast of "Success to the Ealing, Acton, and Hanwell Horticultural Society" was responded to by Mr. R. Dean, the Hon. Secretary, and that of "Success to the Botanical and Horticultural Societies of the United Kingdom" by Mr. Henslow. The hall was decorated in a charming manner by Mr. H. B. Smith, and the proceedings throughout were of the most interesting and satisfactory character. It was announced that the summer exhibition of the Society would take place in the grounds of the Manor House, Ealing, on Wednesday, July 9th.

— A CORRESPONDENT in sending us a schedule of the WIRKSWORTH ROSE SOCIETY, the Show of which is arranged to be held on July 17th, observes:—"Three years back we got up an annual flower show that has grown amazingly. Roses, they said, could not be grown on the limestone here, but they sing a different tale now, and we are bound to have a Rose Show. During my ten years here it is the first Rose Show held during that time in Derbyshire, though not in any way central. We are setting, I think, a good example by showing what out-of-the-way places can do, being only accessible with a single line from Derby—thirteen and a half miles." The schedule contains twenty-four classes, the leading prizes being £5 for forty-eight varieties (nurserymen) and the same amount for twenty-four varieties (amateurs). The interest that is taken

in the Society is exemplified by the provision of twenty special prizes by residents in the district.

MR. SMEE'S ORCHIDS.

THE rapidly increasing collection of Orchids at the Grange, Hackbridge, the "My Garden" of the late Mr. Alfred Snee, and now equally cherished by his son, never looked better than at the present time. Many plants are in flower, and hundreds of others becoming satisfactorily established; while the plants that were placed outdoors during the whole of last summer appear to have been invigorated by the change. The *Masdevallias* are especially strong and producing fine flowers freely, and the *Dendrobiums* that had a long sojourn in the open air flowered distinctly sooner than others that were kept under glass. *Cattleyas* are particularly attractive now. The plants are not large, but the varieties are good and flowers fine, especially *C. Mossiae aurantiaca* and a variety either identical with or closely resembling *C. M. Southgatei*, these with the following producing an attractive display at the present time:—*Cœlogynes ocellata* and *speciosa*; *Camarotis purpurea*; *Cattleyas labiata* *Roezlii*, *amethystina*, *Mendeli*, *Mossiae* (light, distinct, 50 blooms), *Mossiae aurantiaca* (fine, 50 blooms), and a *Mossiae* similar to *Southgatei* (50 blooms); *Cirrheæ viridis purpurea*; *Colax jugosus* and *jugosus grandiflora* (dark markings); *Brassia Keiliana*, *maculata*, and *verrucosa*; *Dendrobium capillipes*, *Bensoniae*, *Findleyana*, *japonica*, *Pierardi*, and *thyrsiflorum*; *Epidendrum alatum*, *evectum* (rich colour), *vitellinum majus*, and *axanthinum*; *Cypripedium barbatum* and *hirsutissimum*; *Lælia cinnabarina*, and *purpurata* (good); *Lycaste Harrisonæ* and *Skinneri*; *Masdevallia ignea superba*, *Harryana*, *Harryana cærulescens*, *Harryana Lindeni*, *Harryana sanguinea*, *amabilis*, *coriacea*, *Estradæ*, *Lindeni*, *peristeria*, and *Wagneri*; *Odontoglossum Alexandræ* (good forms), *cirrhosum*, *cordatum aureum*, *citrosimum*, *Pescatorei*, *luteo-purpureum*, *Roezlii*, and *triumphans*; *Oncidium crispum* (very dark), *concolor*, *fuscatum*, *Krameri*, and *sphacelatum*; *Phalænopsis Manni*; and *Vanda tricolor*.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE PEAR.

AMONGST the fruit trees of our gardens and orchards the first place undoubtedly belongs to the Apple, but opinions may be divided whether the second place is to be assigned to the Pear or to the Plum. The Pear, like the Apple, is made to yield a beverage, yet its fruit, owing to its perishable character, is of little value for preserving, wherein the varieties of the Plum have the advantage. But we very frequently link together the Apple and the Pear. Their fruits have a similarity, and it is noticeable that many of their insect foes are identical. Perhaps it may be said on a survey that the Apple has more numerous enemies than the Pear has, yet the latter is apt to suffer severely through insects which visit it. Seldom, indeed, do we fail to hear complaints from some district of loss occasioned, even when the weather has been not unpropitious. From root to fruit the Pear affords agreeable food to a variety of insects, and their persistency in some cases calls out all the energy and skill of the horticulturist.

It is chiefly those Pears that are trained against walls that are liable to have their roots attacked. After a certain age standards are able to defy the species, which make their approaches in this manner. Centipedes and millipedes are wont to lurk beneath young Pears, perhaps not doing much harm, as they come abroad at night. These may be trapped into little pots filled with decayed roots or damaged fruit, and soot or lime may be sprinkled upon the surface of the soil. As the parent weevils of the genus *Otiorhynchus* are particularly apt to infest fruit trees in houses or against walls, the presence of their maggots at the roots in such situations is a natural consequence. The maggot or larva of the black Vine weevil (*O. sulcatus*), and that of the red-legged or Apricot weevil (*O. tenebrioides*), have been taken at the roots of the Pear, but they are chiefly injurious to softwooded plants. Should they, however, as will sometimes occur, have been abundant about a garden in the beetle state, after these have been dealt with it may be advisable to remove the upper portion of the soil round Pear trees upon walls, and should some be detected as maggots, soapsuds, ammoniacal liquor properly diluted, or a weak solution of paraffin, will be generally sufficient to destroy them.

The wood leopard moth (fig. 97) is not inappropriately so named in English, because the species grows to maturity in wood, and the moth is somewhat leopard-like in its markings. But the Latin name is less suitable—viz., *Zeuzera asculi*, since it is seldom discovered in the wood of an *Æsculus* such as the Horse Chestnut, though often taken upon Ash, Elm, Lime, and Birch, also upon several fruit trees. From a variety of observations I believe it is very partial to the Pear and it is with that tree Miss Ormerod associates the insect in her "Manual" of the hurtful species. The moth is rather sluggish, but is preyed upon in the day by sparrows, and at night by bats, so that their numbers

are thus diminished, fortunately, since each female deposits nearly 300 eggs. She is larger than her companion, and has wings more transparent, the tail being provided with a long ovipositor, by which the eggs are thrust into crannies of the bark. In both sexes the fore wings are white, with numerous well-defined spots of bluish-black; the hind wings are also whitish, but the spots are less distinct. On the thorax there are six large black spots arranged in three pairs. The season for the moth is from June to August, its time of appearance varying, but it is only upon the wing two or three weeks, though the caterpillar life probably continues many months. There is a resemblance between the caterpillar and the moth, the whitish-yellow body having black spots from head to tail. The feet are sixteen in number, and behind the head is a horny plate which aids the creature in its work of driving channels through the solid wood. When it is full grown, this caterpillar is led by instinct to form its cocoon close to the loose bark, leaving a mere film between this abode and the air, through which the emerging moth can easily push its way. The late Edward Newman, in his history of British moths, stated that the leopard caterpillar rarely feeds in trees to such an excess as to destroy them, and added that he had noticed infected trees which were producing more fruit than those quite sound. Such a view would tend to remove the species from the list of the enemies of the Pear. But although this gentleman was a careful observer, general experience is against his theories; for if it may occasionally happen that a tree only slightly touched by these caterpillars yields well, ere long their persistent attacks exhaust its strength, and it shows sign of decline. Again, if the caterpillars do not kill a tree in which they are numerous

Fig. 97.—*Zeuzera aesculi*.

their many burrows in the trunk or branches render the tree liable to suffer from the force of high winds.

It has been recommended to thrust into such holes as are visible bent wires, by which some of the caterpillars may probably be killed, or paraffin might be injected by the assistance of a sharp-nozzled syringe, which liquid will destroy caterpillars should it reach them, and also render the wood disagreeable to them. If any objection exist to the employment of paraffin, either tobacco water or a solution of softsoap might be used with about equal benefit, and some have tried blowing the fumes of tobacco or of sulphur into the holes. Of course all moths seen should be secured.

We proceed to notice next a moth much smaller, and which has a superficial resemblance to the insects of the fly tribe. It is called the Red-belted Clearwing, *Sesia myopaformis*. The moth has transparent wings, black-tipped, and barred with black. The thorax and body are black; round the latter is a bright red belt. It is usually out in June or July, when the eggs are laid upon the Apple and Pear. The trunks of Pears are usually attacked, but the smaller branches of Apples. Though the eggs are mostly distributed, a party of caterpillars are sometimes to be found crowded in a small block of wood. It is seldom, however, that they endanger the life of the trees in which they are bred. It should be added that this caterpillar is nearly colourless; the head is horny, and the body, though slight, is very muscular. It is to be noticed feeding the greater part of the year, but probably becomes partly torpid during very cold weather. In their season of flight the moths should be caught with a small gauze net, where it is wished to prevent the multiplication of the species.

There is a weevil, *Rhynchites alliarie* by name, which, however, does, so far as the evilence before me goes, not much mischief in Britain, though a great deal on the Continent, that has also been called the "stem-borer," from the plan pursued by the female insect. It visits nearly every species of fruit tree, and the Pear is not unfrequently chosen to furnish food for the larva or grub. The emergence of the mature beetle takes place in the summer. This little creature, hardly the sixth of an inch in length, is of a steely-blue or a bluish-green colour, armed with jaws remarkably trenchant. Intent upon her work of oviposition, the female searches amongst the young shoots till she perceives

one that is suitable, upon which she settles, and deposits an egg within an incision or small chamber which she forms. This done, she passes a short distance along the shoot, and by dint of perseverance cuts it off and pushes it to the ground. Sometimes she follows it and deposits a second egg thereupon. She is thus occupied for a week or two visiting a succession of shoots until all her eggs are laid. When the grub is full grown it quits the shoot and enters the earth to become a chrysalis. It is therefore evident that when this beetle is suspected to be in an orchard fragments of shoots lying on the ground ought to be picked up and burnt, and some advise spreading sheets under the trees just when the beetles are busy, into which they may be shaken, and many other insects also injurious.—ENTOMOLOGIST.

EXOTIC PLANTS IN CORNWALL.

THE number of exotic plants, in addition to those named on page 384, which are at home in the open air in Cornwall, is very large and varied, so that scarcely any approximate number can be satisfactorily given. Those which thrive well in one district will scarcely grow in another, although the temperature of both districts may be much the same. The reason can only be assigned to soil and altitude. The various modes of culture (or non-culture) employed by different growers have perhaps a greater influence, one way or another, than most persons are aware of. A great number of exotic plants thrive only in situations where they are allowed to remain for years undisturbed, whereas others require to be taken up and replanted annually. It is by observing such important facts in plant-culture, and which are so often ignored, that success is to be obtained.

Few half-hardy plants are more extensively employed than the ornamental *Escallonia macrantha*. One of its chief uses is as a hedge shrub at Sill, where protection from winds is absolutely needed. It seems to withstand any storm, and for such a purpose it has an excellent companion in the common *Euonymus*. Both are planted when young, and from about 6 inches to 1 foot in height; they rapidly form very excellent fences, and bear cutting well. I prefer the more decided and deeper scarlet flowers of *Escallonia Ingrami*, but this species usually grows to a larger state, and is not nearly so convenient a plant to grow as the commoner one. There is a species of *Escallonia* which is very much neglected and rarely seen in gardens; it is *E. montevidensis*. It has a somewhat scandent habit, and is one of the most admirable of plants for growing against a sunny, but rather sheltered, wall; it makes a somewhat irregular growth, and its pure white flowers are borne in large pendant panicles.

Aralias bear even a moderately severe frost without being at all seriously injured. *A. papyrifera* is one of the best; it is a very handsome plant, and often grows 6 feet in height, and has its five or seven-lobed leaves a foot in length. The decorative value of this fine species is greatly enhanced when its large drooping panicles are produced. Although this species was first cultivated as a greenhouse plant when introduced into this country, it is now generally regarded as hardy. Another handsome species, with large digitate deep shining green leaves, is *A. Sieboldii*; this I have found quite hardy even in Somersetshire, but farther north it requires greenhouse protection during the winter months. *A. trifoliata* is also hardy in Cornwall.

Three species of those curious little shrubby plants, the *Colletias*, are hardy—viz., *C. cruciata*, *C. horrida*, and *C. racemosa*, although both grow very slowly; and only one, *C. horrida*, has flowered among those I have seen. *Convolvulus Cneorum*, with its silvery-white broadly lanceolate leaves and terminal clusters of pale rose flowers, which are hairy on the outside, thrives admirably within a few feet of the sea at St. Michael's Mount, and produces blooms in the early part of spring. Two other most desirable plants which thrive best in well-drained soil are *Eugenia myrtifolia* and *E. Ugni*, the small fruits of the latter being very pleasant to the taste. *Fuchsias*, such as *cordifolia*, *microphylla*, *procumbens*, and *splendens*, in addition to many hybrids, are kept in the open all through mild winters, and apparently form sturdier plants than when confined to a greenhouse. These remarks apply with equal truth to the bedding *Pelargoniums*, and both must be protected from excessive rains. Amongst the many tropical plants grown without success, few are more striking than the gigantic *Musa Ensete*; it survived six winters almost wholly unhurt, but ultimately succumbed. It was in the gardens of E. Bolitho, Esq., at Trewilden, about four miles west of Penzance, and was a well-grown plant several feet in height when transferred to the open air from the conservatory. *Hedychium Gardnerianum* has proved thoroughly acclimatised in various parts of the county, but the handsome yellow-flowered species, *H. flavum*, is not so well known, although equally desirable, and would no doubt prove hardy enough in a light well-drained soil in districts other than Penzance and Sill.

It would be difficult to enumerate all of what are generally considered as stove plants which will be found hardy, or nearly hardy, in the west of England. I believe that I have named the more striking examples, or those calling for special mention. The list, however, would be incomplete if the following names were omitted:—*Abutilons* *Boule de Neige*, *megapotamicum*, *vitifolium*, and *voxillarum*; *Ammobium alatum*, *Benthamia fragifera*; *Banksias* *grandis*, *integrifolia*, and *littoralis* (killed); *Bougainvillea glabra*, *Clianthus puniceus*; *Correas* *alba*, *carnea*, *cardinalis*, and *virens* (mostly severely damaged); *Cassia corymbosa*, *Coprosma Baneriana*, *Ceanothus*, *Chorozema macrophylla* (killed or severely damaged), *Daphne indica* and its varieties, *Edwardsia grandiflora*, *Gasterias*

glabra and nigrescens (killed); Hakeas prostrata and suaveolens (severely damaged); Habrothamnus elegans and fasciculatus; Leptospermum bracteatum (killed or nearly so); Olearias dentata, Haastii, and stellata; Polygalas Dalmaisiana, intermedia, and oppositifolia; Primulas verticillata (killed), japonica, and Palinuri; Phormiums atropurpureum, tenax, and tenax Veitchii; Pittospermum eugenioides, Rocheas falcata and perfoliata (killed); Sparmannia africana and Plumbago capensis (killed); Sedums arboreum (nearly killed), albicans and aureum; and Seaforthia elegans (much damaged). This list is far from exhaustive, but it will serve to show how exceedingly rich the gardens of Cornwall collectively are in tropical, semi-tropical, and other exotic plants. I have good reason to believe that a great number of plants usually supposed to be lost to cultivation would be detected by a competent botanist at Tresco, Scilly.—WILLIAM ROBERTS.

A CARNIVOROUS PLANT.

AN interesting discovery has been made during the last week by Mr. G. E. Simms, son of a well-known tradesman of Oxford. It is that the bladder-traps of *Utricularia vulgaris* are capable of catching newly hatched fish and killing them. Mr. Simms brought to me for examination a specimen of *Utricularia* in a glass vessel, in which were numerous young roach newly hatched from a mass of spawn lying at the bottom. Numbers of these young fish were seen dead, held fast in the jaws of the bladder traps of the plant. I had never seen *Utricularia* before, and am indebted to my colleague Prof. Burdon Sanderson for the identification of the plant and a reference to Cohn's researches on it. Mr. Simms supplied me with a fresh specimen of *Utricularia* in a vessel with fresh young fish and spawn, and in about six hours more than a dozen of the fish were found entrapped. Most are caught by the head, and when this is the case the head is usually pushed as far into the bladder as possible till the snout touches its hinder wall. The two dark black eyes of the fish then show out conspicuously through the wall of the bladder. Rarely a specimen is seen caught only by the tip of the snout. By no means a few of the fish are, however, captured by the tail, which is swallowed, so to speak, to a greater or less distance, and I have one specimen in which the fish is caught by the yolk sac. Three or four instances were observed in which a fish had its head swallowed by one bladder-trap, and its tail by another adjacent one, the body of the fish forming a connecting bar between the two bladders.

I have not been able to see a fish in the actual process of being trapped, nor to find one recently caught, and showing by motion of the fore part of its body signs of life. All those trapped were found already dead, but I have had no opportunity of prolonged observation; and it will be remembered that Mr. Darwin, in his account of the trapping of Crustacea, worms, &c., by *Utricularia*, states that he was not able to observe the actual occurrence of the trapping of an animal, although Mrs. Treat of New Jersey often did so. I think it probable that the fact described by Mr. Darwin, and which is easily verified, that the longer of the two pairs of projections composing the quadrifid processes by which the bladders of *Utricularia* are lined "project obliquely inwards and towards the posterior end of the bladder," has something to do with mechanism by which the small fish become so deeply swallowed, so to speak. The oblique processes, set all towards the hinder end of the bladder, look as if they must act together with the spring valves of the mouth of the bladder in utilising each fresh struggle of the captive for the purpose of pushing it further and further inwards. On cutting open longitudinally some of the bladders containing the heads and fore parts of the bodies of fish, and examining their contents, I found the tissues of the fish in a more or less slimy deliquescent condition, no doubt from decomposition, for Mr. Darwin failed to detect any digestive process in *Utricularia*. The quadrifid processes were bathed in the slimy semi-fluid animal substance, and the processes themselves appeared to contain abundance of fine granular matter, possibly the result of absorption, but the large quantity of surrounding animal matter present rendered the observation uncertain. The usual swarms of Infusoria were present in the decomposing matter.

Specimens of the *Utricularia* with the little fish fast in the bladder-trap, and their heads or tails hanging out, can be well preserved in spirits, and show the conditions well, notwithstanding that the plant becomes colourless, and there is no longer the marked contrast between the glistening white dead fish and the green bladders, which in the fresh condition renders the combination of the trap and prey conspicuous.

Mr. Simms, by whose permission I write this, intends shortly to publish an account of his observations himself. I have advised him to endeavour to prepare spirit specimens of *Utricularia* plants with numerous trapped fish *in situ* for sale to those interested in the matter who may care to apply for them. His address is 37, Broad Street, Oxford.—H. N. MOSELEY (in *Nature*).

IRIS SUSIANA.

THOUGH less brightly coloured than many members of the Iris family, the "Great Turkie Flower de Luce," as this plant was termed by the old writers, is one of the most peculiar and striking of all our garden flowers. When in a suitable situation, rather warm, sheltered, and free from stagnant moisture, the plant grows strongly, reaching a height of 2½ feet, and flowers freely in the early summer months, producing a strange effect in the border. The flowers are of great size, resembling *I. iberica* in form, the ground colour being of a dull grey, upon which are a number of purple markings, which singular contrast has obtained for it the name of the "Mourning Iris." It was well known to Parkinson, who thus describes the plant—"It hath divers heads of long and broad fresh greene leaves folded within one another at the bottome, as all other of the Flower de luces are. From the middle of some one of these heads riseth up a round stiffe stalke two foote high, at the top whereof standeth one

flower, the largest almost but the rarest of all the rest, consisting of nine leaves, but of the colour of a snake's skinne it is so diversely spotted." It was introduced to this country towards the close of the sixteenth century from Persia, the specific name being derived from a city in that country. Some of the old writers state that if the standards of this species are placed in water they produce a fine violet colour; and one adds—"But if a little Allome be put therin, and then wrung and pressed, and the juice of these leaves dried in the shadow, will give a colour almost as deep as indico, and may serve for shadowes in limming excellent well."

CRYSTAL PALACE SHOW.

MAY 23RD AND 24TH.

AN innovation was made at the Crystal Palace last week in arranging the plants. On all former occasions they have been grouped in the transept, and consequently dwarfed in comparison with the magnitude of the building. Under such circumstances it was impossible to display them to advantage, and also the heat and glare in bright weather so exhausting to the flowers that many of them have often lost their freshness almost before the judging was completed. The Show to be noticed, which was unanimously considered the finest that has ever been seen at the Palace, was held in a series of marquees at the extreme end of and outside the building next the aquarium, and so satisfactory was the result that the Directors of the Palace and Mr. Head, the Garden Superintendent, merit hearty congratulations. If it should be possible in the future to find space that can be covered by one monster marquee, and arrange the plants in it in gardenesque style, the attraction would be irresistible, and inhabitants of the metropolis would come in their thousands to enjoy so rich a floral feast. The arrangement of the large tent on the present occasion was so excellent, and the effect so imposing, that it is clear that not only will liberal prizes bring out splendid plants, but that there is no lack of taste to dispose them effectively if adequate means can be provided. We shall hope, too, an extension of accommodation on the lines indicated, and to have the pleasure of inspecting a magnificent exhibition at the Palace similar in character to the world-famed spectacles that are periodically arranged in Ghent and Brussels. The Exhibition of last Friday and Saturday was undoubtedly marred by the sectional method of arrangement, and by the obtrusive stages in some of the tents. These want practically sweeping away, tabling only being required to a limited extent for certain small plants, while the too long endured custom of elevating large ones ought to have received its death blow by the admirable result of grouping the elephantine specimens in depressions in the lawn, where the pots were practically invisible, and the plants were seen to such great advantage.

STOVE AND GREENHOUSE PLANTS.—Prominent in the first spacious marquee were the magnificent stove and greenhouse plants entered in the competition for nine specimens. Mr. Chapman, gardener to J. Spode, Esq., Hawkesyard Park, Rugeley, was the champion with a selection from the specimens of those which two days previously had gained him the premier position in a similar class at Regent's Park. Especially notable was the Veitch Memorial prize plant of *Hedera tulipifera*, which was greatly admired, and is indeed a marvellous example of good culture and careful training. All the plants were large, most of them 5 to 6 feet high and as much in diameter, and splendidly flowered, particularly *Tremandra ericaefolia*, *Erica Cavendishiana*, *Erica affinis*, *Ixora coccinea*, *Anthurium Schertzerianum*, *Ixora Dixiana*, and *Statice profusa*, the *Statice* and *Tremandra* being in most praiseworthy condition, and loaded with flowers. Mr. H. James, Castle Nursery, Lower Norwood, followed very closely with smaller, but remarkably fresh healthy specimens, including *Erica depressa*, very handsome *E. Cavendishiana*, *Azalea Model*, *Anthurium Schertzerianum*, and *Genetyllis hookeri*. Mr. E. Tudgey, Waltham Cross, took the third position, his best specimens being *Erica Cavendishiana*, 7 feet in diameter; *Pimelea decussata*, and *Erica coccinea*, 5 feet in diameter, and beautifully flowered. Amongst the amateurs Mr. Chapman was again first with six specimens equally as beautiful as the others, though on a smaller scale. *Acrophyllum venosum* was admirably flowered; *Aphelexis macrantha purpurea*, very healthy and evenly trained; *Ixora regina*, *Erica Cavendishiana*, *Anthurium Schertzerianum*, and *Tremandra ericaefolia* were also praiseworthy. Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, was a close second with well-grown plants, *Erica depressa* being one of the best in the collection. For a single specimen stove plant in flower Mr. Wakeham, gardener to H. Barrett, Esq., North Dulwich, was awarded the chief prize, his specimen being a beautiful example of *Clerodendron Balfourianum*, 5 feet high and 4 feet across, of globular form, well furnished with flowers. An extra first prize was also accorded to Mr. James for a vigorous plant of *Anthurium Andreanum*, bearing nine large brightly coloured spathe. Mr. Tudgey, who was second, showed a very good *Clerodendron Balfourianum* but slightly inferior to Mr. Wakeham's specimen. In the corresponding class for one specimen greenhouse plant Mr. Rann secured first honours with *Hedera tulipifera*, 4 feet high and the same in diameter, most symmetrical, and in perfect health. Mr. Tudgey was a good second with *Erica ventricosa magnifica*, nearly as large as the preceding, and flowering profusely. Mr. Chapman was placed third with *Erica profusa*, neat and free.

AZALEAS.—These contributed greatly to the beauty of the Show, as, though they were not remarkably abundant, the specimens were with one exception grandly flowered. The chief class was that for nine specimens, in which Mr. C. Turner, Slough, secured premier honours with beautiful plants of moderate size, 4 to 5 feet high, pyramidal in form but not too rigidly trained, and with the richly coloured flowers was to be seen a little fresh green foliage that rendered the plants much more pleasing to many visitors than the masses of flowers which by some are regarded as the beau ideal of Azalea culture. The best of the varieties were Duc de Nassau, Ferdinand Kegeljan, Madame Cannart d'Hamale, Reine des Fleurs, Chelsoni, Comtesse de Flandres, and Stella. Mr. Child, gardener to W. J. Bell, Esq., Garbrand Hall, Ewell, was a good second, some of his specimens being much larger than the preceding and superbly flowered, but the collection generally was

Fig. 98.—IRIS SUSIANA.

less even. Duc de Nassau, 5 feet high and as much in diameter, was very handsome; Concinnum and Flag of Truce were also very notable for their freshness. The same exhibitor was adjudged the first prize in the class for six specimens, showing smaller but well-grown examples; Iveryana 4 feet in height being one of the largest and most imposing. Sir Charles Napier, Reine des Pays Bas, and Duchesse de Caylus were also worthy of mention. Only two collections of eighteen Azaleas were staged, Mr. C. Turner taking the lead with neat, compact, globular specimens laden with flowers mostly large and clearly or brilliantly coloured. Particularly notable were Phœbus, Roi d'Hollande, Cordon Bleu, Reine de Portugal, Apollo, Princess Louise, and Duc de Nassau. Mr. James followed with fairly good plants.

Ericas were not shown very numerous, Mr. E. Tudgey securing the first prize for nine plants with comparative ease, as the only collection entered against him was disqualified for including two plants of *Erica Cavendishiana*, one being named *affinis*, and one of the plants was in a smaller pot than the size stipulated—viz., 12-inch. The Waltham Cross Ericas were very neat and excellently flowered, well deserving their position. The chief forms represented were *E. depressa*, *E. grandiflora*, *E. affinis*, *E. Wilsoni*, *E. ventricosa magnifica*, *E. eximia superba*, *E. Cavendishiana*, and *E. tricolor*. In the amateurs' class for six plants there was no competition.

Though but one collection of Clematises was entered, these had a fine effect in one of the dells of the large marquee, and contrasted most strikingly with the more brilliant Azaleas and stove or greenhouse plants. Messrs. G. Jackman & Son, Woking, were the exhibitors of the twelve specimens for which the leading prize was awarded, and though the plants were principally the same as those exhibited at the Regent's Park Show two days before, they appeared equally fresh and beautiful. The flowers were so large, so evenly disposed over the plants, and of such varied and rich shades of mauve, lilac, purple, and blue, diversified with white and striped flowers, that they attracted much admiration from the visitors.

FINE-FOLIAGE PLANTS.—No exhibition is complete or pleasing without a due proportion of fine-foliage plants, and therefore careful provision was made for them in the Crystal Palace schedule. The most important class was that for nine specimens, in which three close and admirable collections were entered. Mr. C. Rann deservedly won the premier position with even, vigorous, and handsome specimens, comprising a superb plant of *Bonaparteia stricta*, 4 feet high, in perfect health; *Cycas revoluta*, large and vigorous; *Croton Hendersonii*, 6 feet high; *Cycas circinalis* of wonderful size, 12 feet high and in excellent condition; *Spathiphyllum pictum*, finely variegated; *Pandanus Veitchii*, *Dasyllirion acrotrichum*, *Croton undulatus*, and *C. interruptus*. The second prize was adjudged to Mr. Penfold, gardener to the Rev. Canon Bridges, Beddington House, for a collection but slightly inferior to the preceding, and comprising most praiseworthy plants of *Phyllanthus nivosus*, beautifully variegated; *Spathiphyllum pictum*, which is becoming a favourite exhibition plant; *Anthurium regale*, *Dieffenbachia Chelsoni*, and *Carludovica Drudei* 8 feet high. Mr. James was third, also with fresh and healthy plants, one of his best being *Anthurium regale*. A trio of good collections were also entered in the class for six, Mr. Penfold winning first honours for beautiful examples of *Anthurium crystallinum*, *Alocasia macrorrhiza variegata*, *Dieffenbachia Bausei*, and *Thrinax elegans* amongst others. Mr. Rann took the second place, having a gigantic *Areca sapida*, a good *Bonaparteia stricta*, and a large *Phoenix reclinata*; Mr. King, gardener to P. Crowley, Esq., Waddon House, Croydon, being third with well-grown plants, including a large *Asparagus tenuissimus*. The best single specimen was an enormous *Lantana borbonica* from Mr. Rann; this was 8 or 9 feet high, and fully as much across the head. The second was *Areca lutescens*, with four stems 9 feet high from Mr. James; and the third *Pritchardia magnifica*, 8 feet high, from Mr. Tudgey.

FERNS.—Like the preceding, these were represented by some creditable collections, Mr. Penfold taking the lead amongst the three competitors in the class for nine specimens with plants of moderate size, but in excellent health and as fresh as could be desired. *Davallia polyantha*, for instance, is rarely seen at exhibitions in such fine condition, the fronds being of an intensely rich dark green colour, and the plant fully 7 feet in diameter. *Adiantum peruvianum* 4 feet in diameter, *A. cardiochlaena*, *Todea superba*, *Polypodium Billardieri*, and *Davallia Mooreana* 5 feet across were other noteworthy plants in this contribution. Mr. J. Wakeham, gardener to H. Barrett, Esq., North Dulwich, and Mr. James, followed with smaller Ferns, but similarly healthy. There was no competition in the class for six Ferns, Mr. Penfold securing the premier prize with plants that well merited the honour.

DRACÆNAS.—Entries were good in both the classes for *Dracænas*, and the plants generally were well grown. It is to be regretted, however, that in one or two instances there was evidence of attempts to give the leaves a glossy appearance, which cannot be too strongly condemned. Mr. James staged the best nine plants 3 to 6 feet high, well clothed with foliage to the base, and richly coloured. The leading varieties were *Shepherdii*, *Gladstonei*, *Cooperi*, *Regina*, *Mooreana*, *Goldiana*, and *elegantissima*. Mr. Bird, gardener to J. A. Causton, Esq., Allyn Park, Dulwich, was second with sturdy healthy specimens, and Mr. Rann followed with smaller but well-coloured plants. For six specimens Mr. King was worthily first, having very neat and fresh plants 3 to 4 feet high, and most satisfactorily coloured. The varieties were *Gladstonei*, *Vivicans*, *Goldiana*, *Anerleyensis*, *Majestics*, and *Baptisti*. Mr. Wakeham was second with smaller but very compact plants, Mr. Bird taking the third place.

CROTONS.—Though less numerous than the *Dracænas*, these held a prominent position in the Show, and several particularly highly coloured plants were staged. Mr. Bird contributed the premier nine specimens, large and handsome examples of some of the best varieties in cultivation. Several of the plants were 6 feet high and furnished with foliage to the base. Especially fine were *Andreanus*, *Disraeli*, *Weismanni*, *Sunset*, *Nobilis*, *Evansianus*, *Prince of Wales*, and *Queen Victoria*. Mr. James was awarded the third prize for a rather irregular collection, the only first-rate plant being *C. Andreanus*. In the amateurs' class for six, three competitors entered, but there was much difference in the respective merits of the plants, some being old, large, and bare, others much smaller but well coloured. Giving preference to the latter, the Judges placed Mr. Penfold first, his neat little plants comprising *elegantissimus*, *variegatus*, *Queen Victoria*, *Johannis*, and *Weismanni* in beautiful condition. The other prizes were secured by Messrs. Bird and Wakeham.

CALADIUMS were represented by three or four collections of well-coloured healthy plants. Messrs. Laing & Co., Forest Hill, were first with nine specimens, the chief varieties being *Album luteum*, *Luddemanni*, *Madame Hunnebell*, and *Sanchoniathon*. This was the only collection in the open class; but in the amateurs' division there were three competitors, Mr. James Sharpe, gardener to F. Hatchett, Esq., Grove Park, Sydenham, S.E., winning premier honours for beautiful examples of *Meyerbeer*, *Chantini*, *bicolor splendens*, and *Albert Edward*. Mr. Collins, gardener to J. Anderson Rose, Esq., Wandsworth Common, and Mr. W. King, were second and third with smaller plants.

CALCEOLARIAS.—Very rarely is such an extensive display of *Calceolarias* seen at a London show as that at the Crystal Palace last week, and the exhibits proved in the most convincing manner that these handsome greenhouse and conservatory plants have been greatly improved in recent years in a popular point of view. Much difference was, however, manifest in the exhibits, and some diversity of opinion occurred respecting their several merits. The Judges, however, pronounced in favour of the best grown plants, and gave Mr. Ford, gardener to C. J. Leaf, Esq., Pain's Hill, Cobham, the first prize for eighteen plants, wonderful examples of dwarf bushy specimens 2 to 3 feet in diameter, with sturdy healthy foliage and abundant flowers. In comparison with others shown the flowers were not of high quality and were too low on the foliage. Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, followed with smaller plants, but bearing good heads of the finest-marked and best-coloured flowers of all those exhibited. Mr. James, Woodside, Slough, was third with still smaller plants bearing exceedingly richly coloured blooms, and an extra prize was awarded to Messrs. J. Carter & Co., High Holborn, for good plants and varieties. In the class for twelve plants the awards were similar, Mr. Ford taking the first prize with bushy plants; Mr. Salter was second, and Mr. Griffin, gardener to G. F. Coulson, Esq., Farnside, Sydenham Hill, was third.

Messrs. Wakeham, Laing, and Bird showed *Gloxinias* well and took the prizes in that order, the plants being freely flowered, the blooms large and richly coloured.

ORCHIDS.—The contributions in these classes included some plants of great interest and beauty, and could they have been massed together in one tent they would have produced a grand effect. The most important class was that for a group of Orchids, in which there were two entries, Mr. James taking first honours for a highly tasteful arrangement of Ferns, Palms, and numerous Orchids, neatly edged with *Adiantum cuneatum*. Mr. Salter was adjudged the second prize for a very choice collection, comprising many handsome plants, but there was scarcely sufficient foliage to relieve the numerous brightly coloured flowers. In the open class for nine Orchids Mr. James was again the most successful exhibitor with fine specimens, including *Oncidium Marshallianum* with a grand panicle 5 feet high; *Lælia purpurata*, with ten flowers; *Odontoglossum vexillarium*, profusely flowered, of a rich colour; *Cattleya Mendelli*, with fifteen flowers, and several other equally noteworthy plants. Mr. Child followed with finely grown plants. Three admirable collections of six plants were entered, Mr. Salter being adjudged first honours for some very choice specimens. *Dendrobium Wardianum* had twelve well-flowered growths, *D. Jamesianum* fifty to sixty flowers, *Cymbidium Lowianum* two spikes of thirteen and nineteen flowers, and *Odontoglossum citrosum roseum* had seven fine spikes. Mr. Child was second, his best plants being *Aerides Fieldingii floribunda*, with three spikes of twelve branches; *Vanda suavis*, *Oncidium ampliatum majus* with seven spikes; and *Lælia purpurata pallida* with eleven flowers. Mr. W. King was a close third, and in the opinion of some his plants deserved a higher place. *Odontoglossum cirrhosum*, with six spikes, was very handsome; *Oncidium sphacelatum* had six fine panicles; *Dendrobium chrysotoxum* had seventeen spikes; but the most surprising plant was *Sophranitis grandiflora*, with three dozen flowers of excellent colour, one the finest specimen ever exhibited. For a single specimen Mr. James was first with *Dendrobium nobile*, 5 feet across and profusely flowered. Mr. Salter followed with *Cymbidium Lowianum*, bearing a spike of eighteen deeply coloured flowers; and Mr. Child was third with a handsome well-grown *Vanda*, but with the flowers rather past their best.

GROUPS.—The competition in the class for a group of plants arranged in a space not exceeding 200 square feet was confined to two exhibitors—namely, Messrs. Laing & Co. and Messrs. Hooper & Co., who were adjudged the prizes in that order. The first-named had a very pretty group most lightly and tastefully arranged, *Tuberous Begonias* and *Gloxinias* contributing the principal colours, *Caladiums*, Ferns, and Palms being also freely employed, and the margin consisted of *Selaginellas*. Messrs. Hooper & Co.'s group was bright and graceful with *Pelargoniums*, *Azaleas*, *Begonias*, *Torenia*s, *Crotons*, *Dracænas*, and Palms, the margin of *Torenia*s and *Isolepis* having a most pleasing effect.

PELARGONIUMS.—The principal entries in the two leading open classes for these were from Slough, Mr. C. Turner taking first with nine Show and the same number of Fancy varieties. The Show varieties were beautiful plants, 3 to 4 feet across, and evenly flowered, such sorts as *Fortitude*, *Comtesse de Choiseul*, *Mountain of Light*, *Kingston Beauty*, and *Duchess of Edinburgh* being especially fine. The best of the Fancy varieties were *Ellen Beck*, *Roi des Fantaisies*, *Fanny Gair*, and *Princess Teck*. Mr. Wiggins took the third prize in this class with small plants. In the corresponding amateurs' classes for six plants Mr. Little, Hillingdon Place, Uxbridge, was also first both with Show and Fancy varieties, the plants being healthy and freely flowered. Mr. Wiggins followed in each class with smaller plants. For eighteen decorative *Pelargoniums* Mr. Little was again the premier, staging a beautiful collection of plants representing some of the best varieties for general cultivation. Very notable were *Duke of Edinburgh*, *Mauve Queen*, *Madame Thibaut*, *Sunbeam*, *Dr. Driamond*, *E. J. Perkins*, *Triomphe de St. Mandé*, *Lady Isabel*, and *Aurora*. Mr. C. Turner was a close second, and Mr. R. Wells, Sydenham, followed, each showing a selection of varieties.

NEPENTHES AND SARRACENIAS.—Mr. B. S. Williams and Mr. James were the only exhibitors of these plants, the former taking the lead with a choice collection of *Sarracénias*, well grown and including the following:—*Mitchelliana*, *purpurea*, *Tolliana*, *Chelsoni*, *flava maxima*, and *Drummondii*. Mr. James had the best *Nepenthes*, eighteen superb plants of great size and bearing numbers of large handsome pitchers. *Dominiana*, *Hookeri*, and

Mastersiana were uncommonly fine. Mr. Williams had smaller plants, but representing a greater number of the newer choice varieties and hybrids.

ROSES.—Two charming groups of eighteen Roses were contributed. Mr. C. Turner scoring a success with beautiful healthy little bushes, the foliage fresh and vigorous in the extreme; the flowers large without being coarse, and highly coloured. Madame Lacharme, Camille Bernardin, Sir Garnet Wolseley, Mons. E. Y. Teas, Celine Forestier, and Edouard Morren were the most attractive plants. Messrs. Paul & Son, Cheshunt, were a very close second, their plants being equally healthy and with handsome blooms.

TABLE PLANTS.—Competition was keen in the class for eighteen table plants, four collections being entered and extremely close in merit—so close, indeed, that some varied opinions were expressed regarding the awards. Messrs. Hooper & Co. were adjudged the leading position, their plants being very neat and extremely healthy, but included too many with broad leaves to please some tastes. *Dracæna Goldiana*, for instance, would not be tolerated by some persons. Several of the plants were, however, well selected, such as *Croton Weismanni*, *Geonoma gracilis*, *Aralia Veitchii*, and *Cocos Weddelliana*. Messrs. Laing & Co. were placed second with similar plants, very neat and healthy; and Mr. B. S. Williams was third with elegant *Aralias*, *Asparagus plumosus*, *Eulalia japonica variegata*, and others of a similar character. In the opinion of many persons these plants were the most fitted for table decoration of all those shown.

TABLE DECORATIONS.—Some extremely tasteful arrangements of flowers were entered in the class for three vases for a dinner table; Miss Cross, 6, Oxford Terrace, Addiscombe Road, Croydon, being honoured with the chief award for three very graceful stands, each with three branches, lightly filled with *Rhodanthes*, *Centaureas*, *Spiræas*, and *Grasses*, with a base of *Carnations*, *Dipladenias*, and *Pelargoniums*. Mr. J. Chard, Clapham Common, was a close second, having tall stands, somewhat similarly filled to the above, but not quite so light. Mr. Butcher, South Norwood, was third with smaller but neat stands. For one epergne or vase for the drawing-room, Mr. Chard; Mr. J. Lambert, gardener to H. W. Segeleke, Esq., Herne Hill; and Mr. Butcher were the prizetakers in that order. Bouquets and buttonholes were numerous and tasteful, Messrs. C. Hepburn, Chard, Butcher, and Hill being the chief prizetakers.

Messrs. Sutton & Sons, Reading, offered three prizes for a brace of Cucumbers, and several good samples were staged. Mr. C. J. Waite, The Gardens, Glanhurst, Esher, was first with Purley Park Hero, very even and good. Mr. Kendall, Templeton Gardens, Roebampton, followed closely with Model; and Mr. Osman, Sutton, Surrey, was third with Improved Telegraph.

MISCELLANEOUS.—The most imposing group amongst the non-competing exhibits were the Roses from Messrs. G. Paul & Son, Cheshunt, which formed a magnificent bank in the large tent. These comprised the grand specimens of Charles Lawson, Beauty of Waltham, Anna Alexiëff, Edouard Morren, Celine Forestier, Centifolia Rosea, and Comte de Serenye, which have attracted so many admirers at the exhibitions of recent years. An extra prize was awarded for this group, also to the following exhibitors:—Mr. C. J. Salter for four superb plants of *Utricularia montana* with hundreds of flowers, and a group of handsome *Calceolarias*; to Mr. C. Turner for a collection of choice *Azaleas*; to Mr. B. S. Williams for a group of new plants; to Messrs. Carter & Co. for a group of *Calceolarias*; to Mr. Bird for a group of *Crotons*; to Messrs. Laing & Co. for a collection of miscellaneous plants; and to Mr. Chard for baskets of flowers, wreaths of flowers, and floral designs for the table; and to Messrs. Hooper & Co. for collections of *Pæonies*, *Lilies*, and *Irises*.

First-class certificates were awarded for the following plants:—To Mr. B. S. Williams for *Nepenthes Mastersiana*, *Dracæna Lindenii*, *Aralia Kerchoveana*, and *Sarracenia Tollyana*, *Mitchelliana*, *Fildesii*, and *Cypripedium ciliolare*, which have been previously described; to Messrs. J. Laing & Co. for *Caladium Comtesse de Condeixa*, *L'Aurore*, and *Tuberous Begonias Her Majesty*, Mrs. Weekes, Lord Chesterfield, Lady Chesterfield, Distinction, Apricot, Hercules, Mrs. Brissenden, and *Croton gracillimus*.

ROYAL HORTICULTURAL SOCIETY.

FRUIT AND VEGETABLE SHOW.—MAY 27TH.

THE combined attractions of the Fruit and Vegetable Show, and the groups of new and choice plants and flowers submitted to the inspection of the Floral Committee, rendered this meeting one of the most interesting that has been held this year, and it is reasonably expected that the subsequent monthly shows will be of still greater importance and interest.

The first of the series of Exhibitions announced for the present season, to be held by the Royal Horticultural Society in connection with the Health Exhibition, took place on Tuesday last; and though the entries were less numerous in some of the classes than had been expected, the vegetables were all that could be desired, and formed a most interesting feature. This first Show was evidently rather too early for the majority of fruit-growers, and a keener competition may be looked for at the next Exhibition in June. Stages around one-half of the conservatory were devoted to the exhibits in competition, the other portion being gay with groups of flowers and plants shown before the Floral Committee. Twenty-eight classes were enumerated in the schedule, the prizes being extremely liberal in the majority, the highest being £6 for a collection of fruits, and the lowest 7s. 6d., the third prize for two Lettuces.

Collections of Fruits.—Three prizes, value £6, £4, and £3, were offered for a collection of six kinds of fruits, but there was only one exhibitor, Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, who was awarded the first prize for large handsome bunches of Foster's Seedling, which would have been better a week or two later. The Black Hamburg bunches were smaller, but of good colour; Elruge Nectarines very handsome; Stirling Castle Peaches of good colour; Golden Queen Melon very neat, and a beautiful even Queen Pine were the other dishes, and all were good, well deserving the honour they obtained.

Grapes.—The competition was close in the class for two bunches of black Grapes, seven lots being staged. Mr. W. Robins, gardener to E. O. Lee, Esq., Hartwell House, Avleshbury, taking the first position with Black Hamburg, the berries large and well finished, and the bunches of fair size. Mr. Woodbridge, gardener to the Duke of Northumberland, Syon House, Brentford,

was a good second also with Black Hamburg, a trifle less well coloured; and Mr. Fyfe, gardener to W. W. F. Dick, Esq., Thames Ditton House, was third with smaller bunches and berries of the same variety. Eight lots of white Grapes were entered, Mr. Robins gaining first honours with Foster's Seedling in fine condition, beautifully ripened, the bunches large, even, and symmetrical. Mr. Fyfe followed with the same variety, the bunches of good size, but less even and not quite so well ripened; Mr. Miles taking the third position with Buckland Sweetwater, not so ripe as might have been wished.

Strawberries.—Three classes were provided for these, but in only one was the competition at all satisfactory. This was for one dish of thirty fruits, and ten were staged, Mr. G. Thompson, Manor Wells, Croydon House, Hounslow, securing first honours with Sir Charles Napier, large and richly coloured fruits. Mr. Haines, gardener to the Earl of Radnor, Coleshill House, Highworth, followed with even examples of Sir Joseph Paxton; and Mr. Austen, The Gardens, Ashton Court, Bristol, was third with the last-named variety, rather small. For two dishes, distinct varieties, Mr. J. Vert, The Gardens, Andley End, Saffron Walden, won chief honours with James Veitch and Sir J. Paxton, both represented by fine fruits. Mr. Austen took the next place, his varieties being Sir J. Paxton and President, much smaller. Strawberries in pots were very poor, the third prize being awarded for the only collection from Mr. J. Worthing, gardener to A. Moss, Esq., Chadwell Heath, Essex; the variety was La Grosse Sucrée, but the plants were nearly destitute of foliage and the fruits were very poor.

Peaches and Nectarines.—Four dishes of six fruits were entered in the Peach class, Mr. Miles leading with Stirling Castle, large and extremely well coloured. Mr. Robins followed, showing Alexander of fair size, but rather deficient in colour; Mr. Nash, gardener to Dr. Fuller, New Shoreham, Sussex, being third with pale samples of Royal George. Nectarines were not so well represented as the preceding, as only two dishes were staged, Mr. Nash securing the premier position with Violette Hâtive, of fine colour; and Mr. Miles followed, showing Lord Napier scarcely ripe.

Cherries were represented by two dishes from Mr. Miles and Mr. T. Hare, Grantham, who were respectively first and second, the former showing very handsome fruits of Black Circassian.

Melons.—These formed a very large class, no less than twenty-one being entered, and the Judges had a rather severe trial in awarding the prizes. It was also remarked as regrettable that only one class was provided, as the result of green and scarlet-flesh varieties being in competition together must almost invariably be in the favour of the first named, and so it was in this case. Mr. Herrin, Chalfont Gardens, Gerrard's Cross, won the first prize with Chalfont Favourite, a green-flesh variety of good flavour and prettily netted. Mr. Austen was second, showing William Tillery, also a green-flesh in good condition; and Mr. Howe, The Gardens, Benham Park, took the third place with Benham Beauty, a scarlet-flesh variety, a cross between Hero of Lockinge and William I. Messrs. J. Carter & Co.'s prizes for two Melons, Captain Larks and Carter's Emerald, brought one exhibitor, Mr. W. Mead, gardener to Lord Barrington, Beckett Park, Shrivensham, who had two good fruits, Carter's Emerald being well netted.

Miscellaneous Fruits.—This class was specially provided to encourage the exhibition of foreign fruits not included in the other classes, but the response was not very hearty. Mr. Woodbridge was awarded a first prize for a collection of nineteen fruits of *Vanilla planifolia*, beautifully ripened and very fragrant. A similar award was made to Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, for an excellent collection of Apples and Pears in first-rate condition. Four dishes were staged of Uvedale's St. Germain, very large and fresh, six of Cornish Aromatic, three of Sturmer Pippin, two of Cox's Orange Pippin, one of Mannington Pearmain, and one of Annie Elizabeth. Second and third prizes were adjudged to Messrs. Austen and Howe for dishes of Figs, the former having Brunswick large and ripe, the latter good examples of Brown Turkey.

Vegetables.—A surprisingly close and beautiful display of vegetables was provided in the class for eight distinct kinds, seven competitors appearing, and their contributions were so nearly equal in merit that the Judges had much difficulty in determining their position. Mr. A. Waterman, gardener to A. Brassey, Esq., M.P., Preston Hall, Aylesford, was placed first with most praiseworthy examples of Vick's Criterion Tomatoes, Canadian Wonder Beans, Early Milan Turnips, White Italian Onions, Connover's Colossal Asparagus, Culverwell's Telegraph Peas, French Forcing Carrots, and Brown Globe Artichokes, all very even, neat, fresh, and good, but some objected to the collection on the ground that Potatoes were omitted. Mr. Miles was an extremely close second, being but a few points behind the other. His Stamfordian Tomatoes were very handsome, large, and finely coloured. Other good dishes were Tender and True Cucumbers, The Queen Onions, Early Nantes Carrots, Little Gem Peas, Veitch's Extra Early Forcing Cauliflowers, Lady Paget Potatoes, and Asparagus. Mr. Lockie, Oakley Court Gardens, Windsor, was third, showing Reading Perfection Tomatoes exceedingly fine, Queen Onions and Negro Beans being similarly noteworthy.

Asparagus.—A great show of Asparagus was made by the entries in the four classes devoted to it, and there was considerable difference in the respective merits of the exhibits. In the amateurs' class for fifty heads there were seven competitors, Messrs. Cheshire Brothers, 24, St. Botolph Street, Colchester, taking the first position with large, even, and white samples. Mr. F. A. Cole, Colchester, followed with less even specimens; and Mr. J. Stewart, gardener to H. J. Barnett, Esq., Langford Park, Maldon, was third for large and rather coarse heads. In the market growers' class for 100 heads Mr. G. R. Simpson, Plough Lane, Colchester, had the best of the four lots staged; large and handsome heads well blanched. Mr. A. J. Harwood, St. Peter's Street, Colchester, was a close second; and Mr. J. Pompart, Kew, was third with similar examples. Only two bundles of 100 heads of French growth were shown, Messrs. Webber & Co. being awarded the first prize for enormous specimens, some of the stems being 1½ inch in diameter. A class was also provided for fifty heads "grown in the most natural manner" and in the opinion of the majority these were the best of all. Eleven bundles were entered, Mr. Miles taking the first place with neat clean examples, about half the length of the stem being green. Mr. Pitt, Bury Hill, Dorking, was second with similar but smaller heads; and Mr. W. Mead was third, also with "green" Asparagus. The exhibits in these classes attracted much attention.

Cauliflowers or Broccoli.—Here, as in the Melons, it was thought that a

mistake had been committed in not having two classes instead of one, as it is scarcely fair to place these two vegetables in competition together at this time of year. Mr. R. Gilbert, Burghley House Gardens, won chief honours with Gilbert's Late Queen, very large white heads, something in the way of Cattell's Eclipse. Mr. Austen took the second place with good solid heads of Leamington, and Mr. Waterlow was third with neat examples of the Model Broccoli. Some small but beautiful Cauliflowers were unrewarded, but were much admired by several horticulturists.

Tomatoes.—Twelve dishes of these were staged each with a dozen fruits, and some of them were remarkably fine for the season. Mr. Lockie led with Reading Perfection, beautiful even fruits, of handsome rich colour. Mr. Miles was second with Stamfordian, slightly less even, but good in size and colour. Mr. Allis, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, followed with fine examples of Trophy.

Lettuces.—Seven collections of two Cos and two Cabbage Lettuces were contributed; Mr. W. Allan, gardener to Lord Suffield, Gunton Park, being first with Hicks' Cos and Dutch Cabbage, both good solid white examples. Mr. Gilbert followed with Covent Garden White Cos, very fine, and a fair Cabbage Lettuce. Mr. Goldsmith, Hollenden Gardens, Tonbridge, was third with Sutton's Brown Cos and Wheeler's Tom Thumb Cabbage, neat and good.

Radishes.—A good display of these was made by four collections. Mr. G. H. Richards, Somerly Park Gardens, Ringworth, being first with White Turnip, French Breakfast, Wood's Frame, and Red Turnip, all neat even and solid. Mr. C. Waite, gardener to Colonel the Hon. W. P. Talbot, Glenhurst, Esher, was second with Sutton's White-tipped, Round Scarlet, and Wood's Early Frame. Mr. S. Haines was third with smaller examples.

Salads.—Mr. Gilbert won the chief prize for a collection of salads with a tastefully arranged tray of Cos and Cabbage Lettuces, Cucumbers, Sorrel, Mustard and Cress, Olive-shaped Radish, Spring Onions, Vick's Criterion Tomatoes, and Tarragon. Mr. Waite had some good Hathaway's Excelsior Tomatoes, but his other exhibits were much inferior to the preceding.

Cucumbers.—Thirteen pairs of Cucumbers were staged, and Mr. Lockie easily gained the first prize for exceedingly handsome fruits of Royal Windsor, even, clean, about 18 inches long, and bearing a good amount of bloom. Mr. C. Howe followed with neat examples of Challenger; and Mr. S. Haines was third with Purley Park Hero, a pretty Cucumber, which has been frequently noted before.

Mushrooms.—Two classes were provided for these, one for a dish of buttons and the other for a dish of nine fully grown specimens. Mr. W. Warren was first with the latter, beautiful samples of moderate size, and was closely followed by Mr. J. F. Barter and Mr. C. Herrin. Mr. Barter scored a similar triumph in buttons. Mr. W. Warren and Mr. J. George, 10, Victoria Road, Putney, being the other prizetakers.

Cabbages.—There was a wonderful show of these, fourteen collections being entered in the two classes. For two heads Mr. C. Osman, South Metropolitan District Schools, Sutton, was the premier exhibitor, showing compact, well-hearted specimens of Enfield Market. Mr. Goldsmith was second with Sutton's Improved, fine and solid; Mr. Waite being third for Sutton's Reading All Heart. For a collection of varieties, two heads of each, Mr. Mead was first with Webb's Imperial, Sutton's Improved Nonpareil, Cocoa Nut, Wheeler's Imperial, Early Longworth, Early Rainham, and Daniel's Defiance. Mr. J. Vert was second, showing Improved Nonpareil, Carter's Mammoth Beef-heart, Ellam's Early Dwarf, Veitch's Matchless, and Audley End First of All. Mr. Goldsmith followed, showing Cattell's Alpha, Early York, Myatt's Early, Cattell's Reliance, All Heart, and Nonpareil.

COMMITTEES.

FRUIT COMMITTEE.—Present: H. Webb, Esq., in the chair, and Messrs. J. Burnett, S. Ford, G. Goldsmith, J. C. Munstett, C. Ross, G. T. Miles, C. Silverlock, G. Bunyard, H. Howcroft, R. D. Blackmore, and J. Lee. The exhibits before this Committee were not very numerous. Mr. Barter, Lancefield Street, Harrow Road, was awarded a cultural commendation for some fine samples of Mushrooms and spawn. Mr. G. T. Miles, Wycombe Abbey Gardens, showed a dish of Chelsea Gem Peas, very neat, the height being said to be about 1 foot. Mr. Hudson, The Gardens, Gunnersbury House, showed a dish of Duck's-bill Apples, which were determined to be Winter Queening. A number of Melons were exhibited, but no definite award was made for any of them, though Benham Beauty and Mr. McIntosh's Seedling were much admired, and a desire was expressed to see them again. Mr. Howe, Benham Park Gardens, showed a scarlet-flesh Melon named Pink Perfection, a cross between Hero of Lockinge and William I. The flesh was deep, the flavour good, and it was well netted. Eclipse from the same exhibitor was described as a cross between Benham Park and William Tillery. It appeared to be a good green-flesh variety, and was beautifully netted. The fine scarlet-flesh Benham Beauty has been frequently noticed before; it was, however, on this occasion a little over-ripe. Mr. McIntosh, gardener to Capt. N. A. Reeve, Ashby Hall, Lincoln, showed a fairly good Melon, a cross between Bloxholm Hall and Hero of Lockinge; and James McIntosh, Esq., Dunecvan, Oatlands Park, also had a fine Melon named Favourite, or Improved Hero of Lockinge, the result of crossing Hero of Lockinge with Scarlet Gem. It had deep scarlet flesh of fair flavour, and appears to be a promising variety. Mr. Vert, Audley End Gardens, had a dish of Alfriston Apples, fresh and in good condition. Mr. G. M. Breese, Petworth Park Gardens, Sussex, contributed a seedling Melon from Colston Bassett crossed with Golden Gem, the skin being of a fine golden colour, slightly netted, the flesh white and deep. Mr. Gilbert, Burghley Gardens, Stamford, showed specimens of his Late Queen Broccoli, which is to be tried at Chiswick. Mr. Ford, Leonardslee, Horsham, sent examples of his Latest of All Broccoli, which was of very bad colour, quite yellow; and Mr. Eckford, Boreatton Park, Baschurch, Salop, sent heads of Eckford's May Queen Broccoli, large, clear, and white.

FLORAL COMMITTEE.—Present, Section A.—Mr. J. Fraser in the chair, and Messrs. E. Hill, J. O'Brien, J. Dominy, H. Ebbage, H. Williams, H. Herbst, and J. Hudson. Section B.—Mr. Shirley Hibberd in the chair, and Messrs. H. Bennett, W. Bealby, J. James, J. Child, H. Turner, and W. B. Kellock. The groups of plants and flowers were very handsome, especially the magnificent Clematises from Messrs. G. Jackman & Sons, Woking, for which a gold medal was awarded. These were equally as fresh as when shown at the Regent's Park and Crystal Palace Exhibitions

recently, and it need scarcely be said that they were a highly important feature in the conservatory at Kensington. Messrs. Barr & Sons, Covent Garden, also contributed an important group of hardy flowers, for which a silver Banksian medal was awarded. Mr. T. S. Ware, Tottenham, had, however, the best group of the kind, a very choice collection of the best hardy flowers, including large numbers of Pæonies and Pyrethrums, for which a silver-gilt medal was adjudged. Bronze medals were also awarded to Messrs. Kelway & Sons, Langport, for an extensive collection of single and double Pyrethrums, and to Messrs. Hooper & Co. for a large group of Pæonies.

Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, had a collection of Orchids, including a fine dark variety of *Oncidium crispum* with sixteen flowers, a beautiful variety of *Odontoglossum Alexandræ*, *Cattleya Mossiæ*, *Cattleya labiata* Roetzlii, *Masdevallia Harryana sanguinea*, and *Brassia Keiliana*. All these were in good healthy condition. The New Plant and Bulb Company, Colchester, had a group of Japanese Maples, well coloured, *Ixiolirion tataricum*, and *Cypripedium spectabile splendens*, a deeply coloured form. Pansy blooms were contributed by Messrs. H. Cannell & Sons, Swanley; Mr. Eckford; Mr. Knox, 17, Gloucester Place, Portman Square; and Mr. R. May, York, the latter having a pretty yellow variety named Golden Circle. Baron F. De Rothschild, Waddesden Manor, Aylesbury, was awarded a cultural commendation for *Odontoglossum Halli leucoglossum* with seven branching spikes, having from twenty to twenty-four flowers each. W. Vanner, Esq., Camden Wood, Chislehurst, exhibited plants of *Cattleya Mendeli marginata*, a light-coloured variety, and *Cymbidium rhodocharis* with greenish white, crimson-streaked flowers in an erect spike. Mrs. Jonas, New Road, Bedford, showed some ornamental designs on violet velvet formed of Melon seeds, arranged like beads, which were very attractive. J. Fellowes, Esq., West Bromwich, had a plant of *Masdevallia racemosa* Crossi, a peculiar variety with small bright scarlet flowers. W. Lee, Esq., Downside, Leatherhead, was awarded a cultural commendation for a plant of *Odontoglossum mulus grandiflorus* with over thirty large and deeply coloured flowers. Fine examples of *Cattleya Mossiæ alba* with pure white flowers, *Masdevallia cucullata*, *M. tridactylites*, and *M. calura*, small-flowered and curious specimens, were also shown from Downside. Messrs. J. Veitch & Sons staged a handsome collection of double Anemones, and a prettily arranged group of hardy flowers, including *Aquilegias*, *Pyrethrums*, and *Poppies*. For all the above exhibits votes of thanks were accorded; and first-class certificates were granted for the following plants:—

Mimulus moschatus Cloth of Gold (Dean).—A yellow-flowered dwarf variety previously described.

Carnation W. P. Milner (Veitch).—A handsome variety with large, full, pure white, well-formed flowers, very freely produced.

Passiflora Constance Elliott (Lucombe, Pince & Co.).—A neat flower about the size of *P. corulea*, and resembling it in form, but pure white with green stamens.

Cattleya Schröderiana (Baron Schröder and Mr. Salter).—Sepals and petals narrow, of a crimson-purple tint; the lip rich crimson, but differing slightly in the depth of colour in different specimens. It is dwarf and free.

Phaius luridus (Baron Schröder).—A peculiar and striking Orchid, with narrow sepals and petals, bronze brown; lip round, claret-purple, the tube yellow. The plant shown had five expanded flowers on a strong spike, and leaves 1 to 2 feet long.

Ivy Pelargonium Isidore Feral (Bealby).—One of the most beautiful varieties of the section yet shown, the flowers very large, full, bright pink, in a dense truss. The habit is strong but compact, and very floriferous.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Rhododendrons and Arancaria imbricata in Isle of Man.—A letter was read from Mr. Farrant of Ballamoar, describing several plants of *Rhododendrons* of Himalayan species growing in the open—e.g., *R. barbatum* Roylei, Thompsoni, Fortunei, Aucklandii niveum, &c., all remarkable for their fine growth; and a monœcious specimen of *Araucaria*, which bore three male catkins and two hundred female cones.

Wallflower epiphytic on a Black Currant.—Dr. Masters exhibited a remarkable example of a Wallflower which (probably from a seed which had fallen into a decayed spot) had grown and penetrated the pith of its host. It was referred to Mr. Murray for examination and report.

Aucubas "ringed."—Dr. Masters also exhibited specimens of *Aucuba* branches:—(1) Wholly deprived of bark for about 1½ inch. In this a considerable callus had formed on the upper edge. (2) Bark removed in two strips with a ligature across it. In this case the wound gradually healed, enclosing the cord, but produced no thickening above it. (3) Bark just scraped, with ligature as before. The bark on one side died down to the wood, and produced a callus above the string, but not on the other. (4) Bark entirely removed and bound with wet moss. Roots were produced from the upper edge, but being neglected and allowed to dry the whole branch died both above and below the wound.

Silver-leaf Disease in Pomaceæ.—Dr. Masters exhibited branches of the Sloe, the leaves of which showed the same state as is so common with Portugal Laurels, Plums, &c. No cause has yet been discovered, though it is abundant in different members of *Pomaceæ* and in different soils. It was referred to Mr. Murray for examination.

Vine Disease.—Young shoots of Vines were sent by Mr. Blackmore, and were found to be attacked by *Acari*.

Puccinia Buxi.—Mr. W. G. Smith showed specimens of this fungus, which formed pustules on the old leaves, but had scarcely begun to appear on this year's foliage. It was received from Ireland.

Lepidium Seedlings Attacked by Pythium De Barryi.—Mr. Smith described some experiments, planting some seeds in ordinary soil and others in boiled soils under a bellglass. Both came up badly attacked. Seeds steeped in solution of 1 per cent. carbolic acid were shown; some died, and but very few were attacked by the disease. This was thought to show that the spores were adherent to the testa, and not in the enviroining media; but as they were watered with ordinary and not boiled or distilled water it was suggested that the watering may have brought the spores. It was further suggested that the experiment should be repeated with that precaution.

Cones of Larch Proliferous.—Mr. Houston exhibited large branches with cones having the axis protruding. They were more abundant upon the lower branches, and only on a single tree amongst others.

Orchids Attacked by Insects.—Hon. and Rev. Mr. Boscawen showed Orchid

roots, especially of Cattleyas, attacked by grubs. A gall-like protuberance is first formed and the root grows round it. Mr. MacLachlan observed that it was the larva of a hymenopterous insect that should be parasitic, belonging to the Eurytonidæ; and that another, *Isosoma Hordei*, was regarded as destroying Wheat in America. He was disposed to think that it really attacked some other insect which was the real destroyer of the Orchid, but that such insect had not yet been found. He said that Mr. Westwood was inclined to think the reverse, and that these genera are not really parasitic, like others of the same family.

Double Daffodils.—Professor M. Foster moved that a Sub-Committee should be formed, consisting of Dr. Masters, Mr. Baker, the Hon. and Rev. Boscawen, Mr. W. Dod, Mr. P. Barr, and Professor Foster, with power to add to their number, to report on the influences of soil and situation and other conditions causing changes from single to double Daffodils, and *vice versa*, and that the Council be requested to give such facilities in the Chiswick Gardens as may be desirable to enable the Sub-Committee to carry out the necessary investigations.

Hybrid *Sarracenia*s.—The Rev. G. Henslow exhibited drawings of the epidermal tissues of the pitchers of some hybrids raised by Mr. Williams between *S. purpurea* and *flava*, and *vice versa*, and between *S. purpurea* and *Drummondii*. In the former the influence of *flava* was seen in the absence of a special secretive surface characteristic of *purpurea*, but the converse influence in the absence of honey glands on the lid. In the hybrid between *purpurea* and *Drummondii* the glands on the lid were present, characteristic of *Drummondii*, while a special secretive surface also existed, characteristic of *purpurea*.

***Desmids* and *Diatoms*.**—Mr. Henslow described an extraordinary growth of these Algæ, unmixed with any other, which had occurred in his private swimming bath, the temperature of which was kept at 80°, and the water constantly flowing. Volvox was absent, as well as filamentous forms.

CORRUGATED GARDEN ENGINE.—I have seen an advertisement of a garden engine with the tank made of corrugated iron. Can any of your numerous readers say how it answers, also where it is to be procured? as I cannot now find the advertisement.—CRUX.

HARDY FRUIT GARDEN.

Watering.—Most of the fruit is set and swelling slowly. The weather now is apparently "set fair," with hot sunny days, and soil so dry that unless watering be thorough and regular there is considerable risk of an undue quantity of fruit turning yellow and falling prematurely. By far the best method is to water at once, pouring on enough to reach the whole of the soil about the roots, and to follow the watering with a thick mulching of loose litter, so as to check evaporation, and to prevent the hot dry air coming in contact with the soil. Such a process is much better than half a dozen mere surface wettings without mulching, most of which evaporates in an hour or two of bright sunshine. So important do we consider this matter, that most of our labourers have been taken from other work to attend to it. To Strawberries a thick layer of long grass is applied after this watering, for the berries are swelling fast, and must not be left longer without a covering on the soil to keep it from being dashed upon the fruit by the heavy downpour for which we are longing so earnestly. We are, however, well provided for a time of drought with a pond on a hill, whence the water comes through pipes softened and warmed by full exposure to sun and air, and a cesspool containing several thousand gallons of house sewage, to which liberal additions come daily from the household. We mention this in view of showing those who are at a loss for water at this critical time what to do by way of provision for the future. Not every garden can be supplied by a pond above it, but there should be no country establishment without its cesspool and some provision of water. If there are no springs there is certainly the rainfall on buildings and roads, and the land drainage, all capable of accumulation in one or more positions accessible from the fruit garden. Now is the time to consider this matter, and to come to a decision about remedial measures, while the want of water and the baneful effect of drought upon the fruit crop are clearly before us.

Pruning.—Thinning and nipping the new growth of Plums, Pears, and Apples, and disbudding Peach and Nectarine trees, is being done. We are glad to find but little blistered foliage, notwithstanding the recent prevalence of cold north-east winds. Thinning of superabundant lateral growth, especially upon Pears, should always be done when the growth is young, both to avoid exhaustion of the tree and to admit light and air freely among the spurs. Young trees are now growing freely, and demand frequent attention in watering, pruning, and training. The forms to which close pruning is applied are cordons, palmette verriers, pyramids, and dwarf bushes, all which now in course of training should have the tips nipped off the leading branches and stem at 15, 18, or 20 inches, according to the habit of growth, which will afford time for the lateral as well as leading buds to become plump and ready for a forward midsummer growth. Stop, also, and thin spur growths, and do all necessary training as the growth becomes long enough. Promptitude in this matter is important, many a valuable

young branch being broken by high winds for want of timely fastening. Standards and bushes which are not to be kept close pruned must be kept free from crowded growths in the centre, and be examined occasionally for caterpillars, which frequently prove destructive to young growth and foliage. Never rest satisfied with a sluggish or weakly growth in young trees. The reason cannot be difficult to ascertain, for if healthy trees planted in sound well-drained soil fail to make a free strong growth, we may be sure drought or blight is the cause. We may add, however, that looseness of the soil about the roots is always a source of mischief, as also is an undue settling down of the soil, leaving a newly planted tree suspended by its supports with the roots half bare. Newly planted dwarf-trained Peaches and Nectarines should be kept growing freely. "The stronger the better," is our motto for such trees, and if the young leading shoots put forth laterals, select enough of the sides for furnishing the wall, and tie them in. We have often had such laterals well furnished with fruit buds.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Early - forced Trees.*—Trees forced so as to afford full crops of fruit in May and onwards require careful management to insure their bearing good crops, and to keep them in health for a number of years; as, having to make their growth in the winter months and to rest during the latter part of the summer, the chief object is to prevent the wood becoming over-ripe, to which end it is necessary to keep the house as cool as possible after the fruit is gathered by ventilating to the fullest extent and exposing the trees in mild showery weather by removing the roof lights, which will greatly benefit the foliage, doing much to prevent premature ripening of the growth and cleansing it of insect pests. Syringe the trees once or twice a day directly the fruit is cleared off, and well water inside borders, as the trees have yet to mature the buds. As the trees are cleared, all shoots that have carried fruit, and not being extensions, should be removed to make room for the full exposure to light and air of the shoots for next year's bearing, and the full exposure of the foliage to the influence of water through the syringe so as to subdue red spider, which must not under any circumstances be allowed to get ahead. Gross laterals should be stopped; but a moderate extension of these, providing they do not interfere with the light, is advisable from its tendency to retard the ripening of the young wood and foliage.

Second House.—Trees started at the new year will be advanced for ripening, and syringing the trees must cease. A good moisture, however, must be maintained by keeping the floors and borders damped morning and afternoon, and there must not be any deficiency of moisture in the soil at the roots, or the foliage will suffer. Any fruit of the midseason varieties will not be ripe for a few days, hence that not well placed for ripening should be turned up to the light. Fire heat will only be needed in cold wet weather to keep the temperature from falling below 60° at night, and 70° to 75° in the daytime. Air should be given freely and a little constantly at the upper part of the house. It should, however, be borne in mind that suddenly lowering the temperature is unfavourable to flavour, hence a genial heat through the night and on dull days, with free ventilation, favours the swelling and finishing of the fruit.

Succession Houses.—Tying in the young shoots intended for carrying next year's crop and extension growth must have attention. The shoots that are growing too luxuriantly may be pinched, especially the shoots for next year's bearing, when they have grown to a length of 14 inches; but it is well not to pinch the shoots in too much, as it tends to the production of a quantity of spray, which is difficult to restrain and is not favourable to the ripening of the wood. We only pinch extensions that have reached the extremity of the trellis, and strong shoots, so as to form an equal distribution of growth throughout the trees as possible. Stop laterals at the first joint, and allow extension as space admits. Syringe twice daily and water the inside borders thoroughly once a week, the drainage being good, and mulch the surface of the borders both inside and out with short manure. Young trees in course of formation should be properly disbudded, and the shoots retained should be allowed to extend their full length, provided they are evenly balanced. The principal shoots ought to be 12 to 15 inches distance apart, and the shoots on branches for bearing 15 to 18 inches apart; and the soil being stiff the trees will make stout short-jointed wood and afford fruit of the largest size and finest quality. Admit air early, and close early with plenty of moisture in the house. Houses in which the fruit is stoning should be kept at an equable temperature of 60° to 65° at night and 70° to 75° by day, with a free circulation of air; but where it is not wished to accelerate the fruit it is better to allow 5° less at night and keep at 65° on cold dull days, making up for lost time by closing early after the stoning is completed. Keep the foliage free from insects, fumigating for aphides, and red spider and thrips never can make headway if the syringing be properly attended to. Scale should be destroyed by the application of an insecticide.

STRAWBERRIES IN POTS.—For late forcing there certainly are not varieties equal to President, James Veitch, Mr. Radclyffe, Sir Charles Napier, Dr. Hogg, and Cockscumb. These properly forwarded give very handsome fruit of excellent quality. To grow them well they need to be brought forward carefully in a cool house, for in a forcing house and close to the glass the fruit is liable to be scalded, but in a late Peach house, or failing this, a cold pit will answer well, the plants being a good distance from the glass, and where they can have abundance of air at all times. In such a position the flower stalks will be short and strong, and the whole plant have a sturdy growth—such only giving large fruit. Thin the fruit to six or eight on a plant, and feed liberally with liquid manure,

surfacing the pots with short manure so as to keep them cool and moist at the roots, and syringe moderately night and morning until ripening commences. Plants with fruit wished kept back should be stood in a frame behind a north wall, and have plenty of air, with a net thrown over it to exclude birds.

PLANT HOUSES.

Gardenias.—These plants will bear severe pruning after they have flowered; in fact they are much benefited by being well cut back. They grow with greater luxuriance and keep comparatively free from insects, much more so than when the growth is slow and stunted. If mealy bug or brown scale are present syringe the plants thoroughly with petroleum and water at the rate of an ounce to the gallon. If one application does not destroy the insects repeat it two or three times at intervals of a few days. After the plants are thoroughly cleaned place them in brisk moist heat until they commence growing vigorously. When they reach this stage they should be potted. The young stock will be growing freely and must be kept clean, the shoots well stopped, and the strongest tied out towards the rim of the pots if shapely bushes are required. Repot when the plants require it, employing a compost of good loam and sand, or a mixture of peat and loam, for these plants will do well in either. When in active growth *Gardenias* require abundance of water both over the foliage and at the roots.

Poinsettias.—During the autumn and winter these plants are invaluable for the stove or conservatory, and their brilliant scarlet bracts are not surpassed by any plants at that season. They will last nearly double the time in the best position when prepared properly for standing in a much lower temperature than that of the stove. These plants can be grown to perfection in a much lower temperature during the summer months than many suppose. If grown in the stove they are drawn up weakly and ruined, but if gradually hardened to cool treatment after they are rooted they will be dwarf and capable of producing bracts of great size. For an early batch cuttings should be rooted at once, and others at intervals of about a month, but none later than the end of July. In order to achieve the best results it is important that the cuttings be dwarf and sturdy, not such that have been drawn up weakly in strong heat. The cuttings should be taken off with a sharp knife just where they join the old stem, or if these are too long the tops of the young shoots will strike freely. The cuttings should be inserted singly in 2-inch pots filled with sandy loam; a little sand should be placed in the centre of each for the base to rest upon. A good watering must be given, and the plants either plunged in the propagating frame or stood under handlights, kept close and well shaded from strong sun until rooted. As soon as rooted they should be gradually hardened to more light and air, and by the time the small pots are full of roots they may be in an intermediate temperature.

Euphorbia jacquiniæflora.—There is some little difficulty in striking the cuttings of this useful plant unless they are prepared for the purpose before insertion. Cuttings taken from plants growing in strong brisk heat are very difficult to strike, but when taken from plants in a cool house not one need be lost if ordinary care be exercised. The system we follow with success is to place the plants intended to supply cuttings in a warm house, and as soon as they are ready for taking off the plants are removed to the greenhouse for ten days. The cuttings are then taken with a heel or without, according to the length of the young shoots, and inserted thickly in sand in 6-inch pots. After insertion the cuttings are well watered and kept close under bellglasses in a heated structure until rooted. If shaded from bright sun scarcely one will fail to form roots, the old plants being again returned to the heated structure until more cuttings are ready. Directly the young plants are rooted, and before their roots become matted, they are placed singly in 3-inch pots in a compost of loam, sand, and a seventh of manure. They should be kept in heat until established, and then placed in an intermediate temperature.

Thysacanthus rutilans.—Cuttings of this useful plant should now be rooted for winter. Strong cuttings must be selected, and inserted singly in 3-inch pots, and if kept shaded from the sun and in a close frame in heat will be rooted in about a fortnight. As soon as they are rooted pinch out the point of the plants, so that they will form two or three shoots instead of leading with one. By the time they have commenced growth their small pots will be full of roots, and they can be placed in 5 and 6-inch pots in the same temperature as the *Euphorbias*. The same compost will suit them, and in their early stages a little leaf mould is very beneficial.

Habrothamnus elegans.—This and its varieties are very useful for supplying cut flowers, whether grown in pots or planted out to cover walls, and will by this time have ceased flowering, or nearly so. To have them in good condition for next winter and spring they should be pruned back without further delay. If the plants are as large as required, or have filled the space allotted to them, cut them close back, leaving only one or two eyes of last year's growth, as the plants flower upon the young growths made during the summer.

FOUL BROOD—FLOORS AND VENTILATION.

THERE are still many bee-keepers who have but a very inadequate idea of the origin and prevention of foul brood. I

have often stated that stamping out the disease on its first appearance by burning the combs and disinfecting and thoroughly baking the hive, then putting the bees through the purgatorial process for some days, is the most satisfactory way of dealing with the disease. Salicylic acid and carbolic acid are good preventives when judiciously used, but from what I know of the malady I do not believe it will effect a cure where the disease is much developed. Some people have spread an opinion that if bees have access to Willows the larvæ will have an immunity from the disease. Such people seem to be unaware that salicylic acid, though extracted from the Willow, is not chemically the same as either the honey or pollen derived from its catkins.

It is now nearly a quarter of a century since my experiment in propagating foul-brood fungi with milk appeared in the pages of this Journal. Some idea of the potency of these germs may be gained when I state that after I exposed them to a boiling heat, then hermetically sealing the vessel containing them, exposing it to the weather for some years, after drying the residuum and keeping it in that state for several more years, I reproduced the same forms as at first. Humidity within the hive is very favourable to the development of foul brood, as is also a close atmosphere. To avoid these the greatest care should be exercised.

Many years since through this Journal, I suggested that floors of hives should be constructed of some other substance than wood, hinting that charcoal might be substituted, but none responded to my suggestions. Previous to that I had been trying different materials that would be less absorbent of moisture than wood, but after many trials I found there was nothing so useful as perforated zinc, and my best hives were those so fitted. I never found a bee chilled on them. They were far less conductive than damp wooden floors; the perspiration from the bees and other matters all passed through to the under sliding floor, so that the bees were at once relieved from the labour of cleaning out the latter and from the offensiveness of the former. These ventilating floors are also very serviceable and of great importance to the good management of bees—for example, during snow, when it is necessary to confine the bees. The first mild sunny day in spring a hive is much benefited by giving a good ventilation for two hours during the warmest part of the day, while it is absolutely necessary during hot weather in summer that bees should be well ventilated from beneath. It prevents crowding out, allowing the bees to work with freedom, prevents the collapsing of combs and incipient foul brood by overheating, and is an absolute necessity in transit, such as when bees are taken to and from the Heather. It will, perhaps, astonish those who are in favour of thick close-fitting floors, that for many years my most forward hives were those that stood all winter with a large space of ventilation beneath. Moreover it is the practice of many of the most successful Scotch bee-keepers to so ventilate their hives during winter. The practice of under ventilation and insensible upward ventilation is of Scotch origin, and has been followed for nearly forty years in my apiary, while a system on the same principle has been carried out from time immemorial in the Stewarton hive. Hives so managed will, as a rule, be free from many evils found in neglected ones, not the least being that of foul brood, which damp and overheating principally cause. The foregoing hints will perhaps assist the unprejudiced bee-keeper who may be in possession of Italian bees, which require more room and air than the common variety, but for which many bee-keepers have made no allowance: hence I believe the cause of cases of foul brood which would have been avoided had the bees been domiciled in suitable hives. If bee-keepers would exercise more judgment instead of following every interested person, and study the nature and requirements of the honey bee, they would not only save much expense, but get much more satisfaction.—A LANARKSHIRE BEE-KEEPER.

LIGURIAN BEES.

ONCE upon a time, as the story goes, a philosopher (so to term him) in a fit of deep meditation was struck by the fact that all great and prosperous cities are situated on rivers; and on mature reflection this coincidence appeared so remarkable that our philosopher put pen to paper, and out of the sublime depths of his inner consciousness evolved a ponderous tome on the subject, and which, if memory serves us, gained a wide circle of readers at the time. It may be that certain carping critics will take offence at our ranking our author a philosopher at all, and that they would rather be inclined to class him, to use the phraseology of an American humourist, a "phool!" In which case we penitently confess our error, and exclaim in the words of Monkbarns, "Well hast thou spoken." The cause is patent to all except to our ph—. Still, we will not be too harsh under the circumstances, remembering, too, as the author of "Hero Worship" tells us, that the latter genus comprises no unimportant part of the population of these happy isles.

I have received numerous communications from apiarian readers of the *Journal of Horticulture* as to my experience of Ligurians as contrasted with our brown bees, but I have little to add to the remarks given in page 116 of my bee book. I have now no Ligurians in my apiary, and I have good reason to add that it is very unlikely I shall ever have any again. They winter badly, are more liable to dysentery than our brown bees, are of decidedly less value as honey-gatherers; are more troubled with the swarming mania; are much addicted to robbing other stocks, even when a honey glut is on, in preference to gathering stores in the natural manner abroad; are more revengeful under provocation. In fact, their ferocity makes them a nuisance in the apiary and to neighbours as well. Often hath the complaint been made to us by some rustic neighbour, "Please, sir, one o' yer yaller bees jest hev stung our Sal, or Tom, and she (or he, as the case may be) had to stop t' ome all day (from school) in consekens."

The worthlessness of Ligurians as a honey-gathering variety has been long recognised by most of the leading practical apiarians of the day—apiarians, that is, whose business it is to raise honey for the market, and who do not raise Ligurians for sale. "I cannot at all imagine," said a visitor in looking over an apiary of brown bees last season, "how it is that your brown bees get so much more honey than my Ligurians. It was just the same at Mr. —'s apiary where I called yesterday. It is really very remarkable." And yet the gentleman was a philosopher too.

I know of two highly prosperous apiaries in this county where the supering system is followed, one of which is situated some twenty miles distant from my place, the other ten. Not a Ligurian is in either. Neither of the proprietors court publicity. The former wrote me last autumn that one of his brown stocks had yielded the splendid harvest (in supers) of 124 lbs. of honeycomb, while several others gave supers of 50 to 60 lbs. each.

It is to be feared that Ligurians have done much to make bee-keeping unpopular. To an unprofessional they are so much more difficult to manage than our indigenous variety of the *Apis* family. That this opinion is not shared by all I well know. An enthusiast (who had Ligurians for sale—but this is by-the-by) at a certain bee show in this county some two years since, after referring, *sotto voce*, compassionately to a friend on our lamentable ignorance on the subject, he sententiously assured us at parting "that not only do Ligurians gather more honey than blacks, but, sir, their honey is of a much better quality too!" Could the force of folly any farther go?

We have at various times received letters from bee-keepers, thanking us for cautioning them at the outset of their career against Ligurians, and contrasting the results in their apiaries of brown bees with those of Ligurians in their neighbours' apiaries.—AUTHOR OF "BEE-KEEPING PLAIN AND PRACTICAL."

SUPERING HIVES—VICIOUS BEES.

FOR more years than I need name I have kept bees, but only lately have I tried bar-frame hives. There are various points on which I, and many like me, would be very glad to have some information. Only one question now, What is the best way to put supers on bar-frame hives? A few days ago I put on one—twelve 2 lb. sections, but by the time I had the quilt off I think the bees were more savage than I have ever seen bees before. I did not like my surroundings at all, and duly considering my two eyes and 20,000 bees *cum talibus* I was glad to finish and beat a retreat as quickly as possible. We do not like old friends suddenly changed in that way, and stinging arguments are to most of us objectionable. Perhaps I ought to write to the *Bee Journal*, but as I see it only occasionally, and yours regularly, I thought I might trouble you. Moreover, the information sought, if given in the *Journal of Horticulture*, will probably reach the class of persons I have especially in view.—PHILOKEPOS.

[Your correspondent "Philokepos" wishes to know the best way to put supers on frame hives. The question itself is simple, but judging from the tone of his letter the answer requires amplification. Many of the modern bee-keepers and dealers in hives are comparatively ignorant of the science of apiculture, through which they have condemned some of the best properties in hives, and have introduced and advocated questionable changes apart from the recognised system of scientific apiculture, as, for example, in the Stewarton hive with its slides. By their use the quilt can be put on and taken off without a bee escaping or being irritated. Moreover, by their use the supers escape the invasion of the queen, and draught is prevented from passing up through brood nest, as well as the vitiated air which discolours the comb, while the operator can place supers with an entire immunity from stings, and no superfluous queen-excluder is necessary.

The quilt, as the pages of this *Journal* can prove, was the idea or invention of "A Renfrewshire Bee-keeper," Mr. Langstroth, and myself a quarter of a century since, but its use was in combination with slides, which have been condemned by some bee-keepers, but in my opinion are very necessary, not only in the Stewarton but in frame hives.

My frame hives have lateral slides, which give me complete control over my bees, especially if a little carbolic acid is used. In hives with drawing slides, such as in the Stewarton, a great mistake is having them made too slack; the bees fill the opening with propolis, and then the slides become unworkable. They should be made neat-fitting, then there is no difficulty in working them. The propolis of the slides was the only objection the modern bee-keeper had, but unfortunately, with the badly made white pine frames and very objectionable narrow top bar quilts, were 100 per cent. more propolised than slides ever were, which when

removed so irritated the bees, that not only is it inconvenient, but highly dangerous manipulating such hives.

When supering hives the first thing to observe is that the day is warm and bees getting honey. If at all cold they sting readily, and do not forget to do so. If quilts are on have a sponge or a wing saturated with carbolic acid, raise the quilt gently at one side, rubbing the tops of the bars slightly with the acid (the bees retreat from it); repeat the process as the quilt is raised. When removed place the supers on the top of the hive and cover well; but before placing the supers it would be advisable to have thin adapting boards underneath them and on the top of the frames, with openings at the outside combs only. Better still if these adapting boards were in pieces; but best of all if there was a lateral slide for every frame, which may be close, or just as much open as to allow insensible upward ventilation, when not a bee can escape. The quilts are then neither gnawed nor propolised by the bees, and the bee-master need have no fear of infuriating them, because the quilt can be removed or placed at any time with pleasure, and not a bee escapes.—A LANARKSHIRE BEE-KEEPER.]

FOUL BROOD.

I AM sorry I have to again trouble you. Last autumn I asked if some of your correspondents could give me through the *Journal* a receipt to cure foul brood in bees, and one or two were inserted, which I put in practice and carried out to the letter. I was, however, again disappointed the other day by finding several cells still in the hive containing foul brood. Will you kindly tell me what I had better do with them? I am spraying them with salicylic acid, and they are all fairly strong, one or two covering ten frames.—FREDERICK BULL, *Gardener, Brymbo*.

[Salicylic acid is a better preventive than a cure, and is only successful in the treatment of foul brood in the hands of the experienced. The best and most satisfactory treatment now, seeing that the hives are pretty strong, is to swarm them when ready. After three weeks separate the remaining bees from the combs, put the bees into a clean new hive, or one that has been disinfected, then consign the combs to the melting pot, and subject the hive to the fumes of sulphur after it has stood in a moist place (with a temperature of not less than 60°) for at least eight days. After that again disinfect with a solution of salicylic, carbolic acid, or permanganate of potash.]

FERTILE WORKERS AND QUEENS IN WORKER CELLS.

"A LANARKSHIRE BEE-KEEPER" (page 392), gives his testimony as to queens and fertile workers living peaceably together. Perhaps he has not read the account of my experiments in the "*British Bee Journal*" pages 66-7, vol. xi., where I introduced black queens to colonies having Syrian fertile workers, and had black workers and Syrian drones hatching side by side for six weeks after, which must be taken as conclusive evidence of the fact. Mr. B. F. Carroll, of Texas, U.S., has been writing this year in the "*American Bee Journal*," and "*Gleanings in Bee Culture*," giving evidence to the same effect, but he does not appear to have made a conclusive experiment to settle the point, and may have read or heard of mine, which of course I cannot say; anyhow, I believe I was the first to discover or satisfactorily settle this interesting and valuable fact. No doubt "A. L. B. K." will be interested to hear that I can bear testimony to queens being reared in worker cells as he describes, having seen several of them, and curiously enough I mention this fact in the "*British Bee Journal*" for May 15th, page 167—the very date his is published in this *Journal*.—JOHN HEWITT, *Sheffield*.

TRADE CATALOGUE RECEIVED.

W. P. Laird & Sinclair, Dundee.—*Catalogue of Florists' Flowers*.

TO CORRESPONDENTS

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Peach Tree Unhealthy (E. T. J.).—There is little doubt that the root-action of the tree is defective, and whether it is planted out or in a pot

fresh turfy loam and a surface dressing of manure appears to be needed. If this cannot be given now, apply liquid manure copiously. Has the tree been overcropped? Are there lenses in the glass above it? Whether there is or not, slight shading is advisable to arrest evaporation, as the moisture is evidently escaping from the foliage more rapidly than it is supplied by the roots, and hence the collapse of the leaves.

A Peculiar Gloxinia (J. H.).—The flower is a singularly formed one, the outer divisions of the corolla being exactly like petals, the true corolla being perfect, and much rounder than usual. The variety is well worth preservation, though we should think it probable that the flower is an accidental and not a permanent departure from the ordinary type.

Bleaching Celery (J. E., Burnley).—We presume you mean blanching, which is effected simply by banking fine soil round the stems when they are large enough also dry; cocoa-nut fibre refuse, ashes, sand, moss, leaves, or indeed anything that excludes the light answers the same purpose, but ordinary soil dug from the sides of the trenches, and if heavy broken up into fine particles, answers all ordinary purposes.

Thrips on Vines (C. G. Fleetwood).—The leaves you have sent are attacked by thrips, but not seriously, and by prompt measures you may prevent the insects doing any injury to the Vines. Thrips may be destroyed by fumigating on two consecutive nights, repeating the process in a week or ten days; but as probably only a few of the leaves are attacked we should sponge them with a solution of nicotine soup, Gishurst compound, or any approved insecticide of the strength named by the vendors, which is two or three ounces to the gallon of water. A handy man will sponge hundreds of leaves in an hour, and prevent the increase of thousands of insects by destroying the few now established.

A "New Fuchsia" (R. H. Spencer).—The plant is *Eucharidium grandiflorum*, and though related to the Fuchsia in a distant degree it is too widely removed to render your statement that it was "raised from Rose of Castille Fuchsia" in the slightest degree probable. We have heard of a person who believed that the yellow Abutilons had been obtained by crosses with some of the Allamandas, and possibly it would have been as difficult to convince him that his ideas were not strictly accurate as it would be to controvert such a positive assertion as that with which you have favoured us.

Collecting Plants (Collector).—If you write to Mr. Smith a month or six weeks before you intend leaving the nursery it will no doubt be sufficient, and if your intentions are clearly stated there will be little difficulty with regard to passing through the different departments. Steady application to your work and studies will obtain you friends there who will assist in your efforts. Lindley's "Descriptive Botany," published by Bradbury, price 1s., contains a great number of terms employed in the description of plants.

Cocoa-nut Fibre Refuse for Roses (J. P.).—It is good as a mulching for Roses, and encourages surface-rooting when thick enough for keeping the soil continuously moist. If the soil is rich, or the plants are well supported with liquid manure, Roses can scarcely fail to flourish when the beds are covered with this material in summer.

Setting a Boiler (A Reader).—If you possess no technical knowledge on the subject of setting boilers, and your bricklayer does not understand the work, it is not easy to make the subject clear to you without illustrations. The best advice we can give to you is to write to the makers of the particular boiler to which you allude, and they will possibly be able to supply you with an illustrated circular, or will otherwise give you the details you need. If they fail to do so you may write to us again and we will assist you as far as we can.

Cuphea platycentra for Bedding (A. B.).—This is the name of the plant of which you have sent a spray. Your plants inserted closely together in a small bed near a walk would have a pretty effect; but they would scarcely be effective in a vase 20 yards from the front of the house. For such a vase and position Pelargoniums and Petunias would be more suitable. Some small beds of Cupheas were much and deservedly admired at Kew last year. They were only about 2 feet in diameter, and, being close to the walk, the thousands of bugle-like flowers could be seen to advantage. Had they been 20 yards from the walk their beauty would have been practically "lost in the distance."

Single Dahlias (Idem).—Plants now 3 inches high, strong and established in pots, will flower freely during late summer and autumn if planted in good soil and well supplied with water, and the surface of the ground mulched with manure. The plants may be either secured to stakes in the ordinary manner or pegged to the ground, the position suggesting the best method to adopt. If intended to be pegged down they are best inserted in a slanting direction, and take particular care that the soil in the pots is not dry at the time of planting.

Second Crops of Melons (L. M.).—If you have never been able to obtain two crops of Melons from the same plants it does not follow that they are not obtainable. On the contrary, we have had many second crops, and sometimes these have been even better than the first. For insuring this the plants must be early, and the first crop ready, say, early in July; there must be a good command of heat and good cultural attention. The plants must not be dried off in the manner that some cultivators deem necessary for ripening the fruit, but must be kept steadily growing, the foliage always fresh, and no red spider or other insects permitted on it. After the first crop is cut a slight pruning and rearrangement of the growths may be needed, and a little of the surface soil removing from the bed, fresh being added to incite the formation of fresh roots. These produced, the rest is easy, amounting to a repetition of the treatment by which the first crop was produced. When the first ripe fruits are removed the plants grow freely, and soon commence flowering. Space must be afforded for the newly developing leaves, some of the older, which will be fading, being removed for that purpose. We do not approve of withholding water from Melons to improve the flavour; healthy active foliage well exposed to the light and air is far more effectual in imparting flavour to the fruit than dry soil is and withered leaves.

Insects on Plants (H. S. P.).—You ask, "How is it that your plants are

so infested with green fly?" We are bound to answer, it is by neglect of the cultivator. When such plants as Pelargoniums, Fuchsias, Petunias, and Abutilons are infested it is quite certain the grower of them has not comprehended the importance of fumigating and syringing with insecticides in good time; and no man who permits insects to gain the ascendancy in the manner suggested can hope to be a good plant-grower. As we have repeatedly stated, the best cultivators of plants never allow any insects on them. They syringe and fumigate to prevent them; and if by chance one or two should be seen there is no rest until they are exterminated. When insects are so numerous as in your case they can only be eradicated by very frequent and rather strong fumigations, or repeatedly syringing them with some insect-destroying solution; and when such strong measures have to be resorted to, there is a liability of some of the plants being injured. You had better procure some tobacco water or some of the insecticides that are advertised, and syringe the plants thoroughly with them according to the directions on the bottles or packages. Those very much infested should be laid on their sides on mats or grass, and turned round to enable the solution to be applied to the under sides of every leaf. This must be no mere sprinkling but a thorough washing, and the next day the plants should be well syringed with pure water, then, when dry, fumigated once a week to keep them clean. We suspect you allow the plants to get too dry at the roots, and keep the atmosphere of the house too dry also; in a word, you appear to be afraid of using water, and consequently become a friend of the insects, which appreciate your treatment, and increase and multiply accordingly.

Liquid Manure for Cucumbers (Idem).—When the pots are crowded with roots and the plants bearing freely liquid manure is of great advantage. Guano at the rate of about half an ounce to the gallon of water is an excellent stimulant, so also is soot water. You should also top-dress with lumps of turf and manure, piling them on the soil and keeping them constantly moist. You would then increase the number of roots to absorb the food supplied, and the plants would increase in vigour accordingly. Keep them scrupulously clean and maintain a moist atmosphere.

Planting Carpet Bed (E. Mason).—As you say you have "plenty of Alternantheras and all kinds of plants," and wish to plant a round bed 8 feet in diameter effectively on a plan somewhat similar to the sketch you have submitted, possibly the annexed design will meet your requirements. It is of a "scroll pattern," and certainly better than the outline

you have prepared. This bed may be planted effectively as follows:—1, *Alternanthera amœna*; 2, *Leucophyton* or *Antennaria*; 3, *Alternanthera paronychioides*; 4, a groundwork of *Herniaria* or *Mesembryanthemum cordifolium variegatum*; 5, raised about 5 inches, and the slope planted with *Echeveria secunda glauca* interspersed with *Sedum glaucum*. Such an arrangement well carried out would have a good appearance, but the design might be rendered equally pleasing by a different method of planting, and on this matter you had better exercise your taste in accordance with the plants at your disposal.

Planting Flower Bed (E. P.).—You ask "whether it is better to commence at the outside and finish in the centre in planting a round flower bed, or to start in the centre and finish on the outside, as there is a conflict of authority on the point." As usual, when two extreme courses are advocated the safe mean lies between them, and you will not err if you first plant the outside row, or perhaps two rows round the bed, and then commence in the centre, arranging the plants to meet those round the margin. By finishing on the outside such neat and regular margins cannot be had, while working always to the centre is often inconvenient. In the London parks one or two outside rows are invariably planted first, and it would be difficult to find a neater and better disposition of the plants.

Hot Water for Plants (M. D.).—The paragraph to which you refer is probably the following, but whether hot water is as potent as represented in reinvigorating plants we must leave you and such other readers as may be interested to test the matter, proceeding cautiously and experimentally:—"M. Willermoz, in the French 'Journal of the Society of Practical Horticulture,' relates that plants in pots may be treated with hot water when out of health, the usual remedy for which has been repotting. He

says when ill health ensues from acid substances contained or generated in the soil, and this is absorbed by the roots, it acts as a poison. The small roots are withered and cease their action, consequently the upper and younger shoots of the plant turn yellow, and the spots with which the leaves are covered indicate their morbid state. In such cases the usual remedy is to transplant into fresh soil, clean the pots carefully, secure good drainage, and often with the best results. But the experience of several years has proved with him the unfailing efficacy of the simpler treatment, which consists of watering abundantly with hot water at a temperature of about 145° Fahrenheit, having previously stirred the soil of the pots so far as might be done without injury to the roots. Water is then given until it runs freely from the pots. In his experiments the water first came out clear, afterwards it was sensibly tinged with brown, and gave an appreciable acid reaction. After this thorough washing the pots were kept warm. Next day the leaves of two *Ficus elastica* so treated ceased to droop, the spread of black spots on the leaves was arrested, and three days afterwards, instead of dying, the plants had recovered their normal look of health. Very soon they made new roots, immediately followed by vigorous growth."

Names of Plants (*An Old Nantwich Subscriber*).—*Menyanthes trifoliata* the Buckbean, related to the Gentians, and remarkable for its intensely bitter taste. In the north of England this plant has, in a scarcity of hops, been used to give a bitter flavour to beer. (*G. B.*)—*Staphylea colchica*. The specimen was much withered, but resembles *Genista tinctoria*. (*Young Gardener*).—1, a variety of *Lantana*; 2, *Lippia citriodora*; 3, *Asplenium Trichomanes*; 4, *Hibiscus Rosa-sinensis*; 5, *Cyperus alternifolius variegatus*.

COVENT GARDEN MARKET.—MAY 28TH.

A BETTER trade doing this week, goods being cleared more readily without any alteration in price.

ARABLE AND PASTURE FARMING.

A COMPARISON between arable and pasture farming, or, in other words, a comparison between corn and stock farming, may be fairly considered one of the most vexed questions of the period. It has, however, always proved a difficult question to be decided, and it still continues surrounded by the same difficulties, for although the prices of stock have risen and the value of grain greatly reduced, yet this cannot be made the measure of profits and loss. The disturbing influence of the seasons, the loss by foot-and-mouth and other diseases, the modes of management, and the practical knowledge required both in breeding, rearing, and feeding of live stock, and the nature of the soil and climate, together with the conditions of management as compulsory and connected with farm leases, as well as hundreds of minute points connected with the farm, render any reliable account in figures one of the utmost difficulty.

Although we have no desire to exaggerate the requirements of the occupiers of arable farms, or those of a mixed character containing grass or pasture land as well as tillage land, yet we must mention a few of the impediments which meet the farmer at almost every step. As an unmixed farm of arable land only is quite the exception, we must speak of the subject as one in which agricultural produce generally, as well as live stock of various kinds, are generally considered as essential in practical farming of arable land. It is not our intention to question the justice or fairness or otherwise of various

difficulties by which the farmer is surrounded, yet they must not only be acknowledged but provided for as matter of business to which his calling has pledged him. We must therefore only mention a few of the most important points which will occupy his attention.

The farm should be taken at a fair rental, together with tithes and rates, the former having lately fallen and the latter increased. The term of years, the conditions of lease, and the liberty of cultivation should be as great as that of the market gardener, many of whom began business with little more property than their working tools, yet these men are bound to no course of cultivation. Why should the farmer, except on quitting? The nature of the land and the climate in which it is situated may well be made the subject of estimate by some experienced farmer or land valuer, especially as the basis of proceeding in taking a farm by young men and beginners in agriculture, at any rate; the rotation of farming being extremely important in order to secure the tenant facility in culture and cropping and the landlord a clean and fair face upon the land at the time, of tenants quitting is a matter not to be hastily decided. The question of a sufficiency of capital is of the highest importance, and it becomes still more so if large flocks and herds are considered a necessity. The supply of local labour, too, either by cottage on the farm and rented therewith, or in connection with a village near at hand inhabited principally by people inured to agricultural pursuits is a positive necessity, for no farm can be conducted with advantage depending only upon casual labour.

The subject of "Arable and Pasture Farming" was introduced last winter at the Kingscote (Gloucestershire) Farmers' Clubs by Mr. Bowen Jones, who read a paper on this subject, which was given by the *Wilts Standard*. In that it is stated:—"A decade of unparalleled depression in the chief industry of the country has set many minds thinking. Advice of all sorts and descriptions has been showered upon the unfortunate agriculturist. The development of the United States of America, of Canada, and India, with respect more especially to the growth of cereals, and Wheat in particular, has produced a gradual, but in the aggregate a considerable fall in the value of these commodities. To all appearance this reduction is likely to be of a permanent character. As shown by the printed averages, and till the present year, and to some extent even now, these returns are an exaggeration on the prices realised, in my opinion something like 5s. per quarter, owing to the defective way in which the corn returns were calculated. On the other hand a comparison of the average prices of butchers' meat, as exemplified by returns of the Metropolitan Cattle Market, will show that a gradual but well-marked increase has taken place, notwithstanding the long-continued distress that has affected the commercial interests of the kingdom. Surely the high averages of recent years should have stimulated farmers to have bred and fed more stock, but an examination of the recently published agricultural returns shows us that this is not the case. These figures give us anything but a pleasant prospect or a hopeful outlook. We find that the total area under cultivation and grass has increased during this period from 31,266,919 acres to 32,385,085 acres, or 1,118,166 acres, while in the same time arable land has diminished 769,295 acres, and permanent pasture extended 1,887,361 acres. In 1874 corn crops bore a per-centage of 30.2 to cultivated and grass land, and in 1883 the per-centage was 26.6. Notwithstanding this enlargement of grass land area our cattle have decreased 162,712 head, and sheep 5,245,670, which gives for every 100 acres of cultivated and grass land in 1883, as compared with 1874, a diminution of cattle 1.2, sheep 19.8. What do these figures illustrate? 1st, That British farmers should and do recognise the fact that they must look to some other source than the growth of cereals alone for direct profit. 2nd, That the high range of prices for butchers' meat indicates an important direction to which they should turn their attention. 3rd, That the recent abnormally high prices of meat, while irksome to the consumer, have not benefited the farmer."

The preceding indicates the delusions under which farmers in general are acting, as it is shown that the high prices of meat, while irksome to the consumer, have not benefited the farmer. Another delusion is it being inferred that the high range of prices for butchers' meat indicates an important direction to which they should turn their attention. Nor can we see that the farmers should recognise the fact that they must look to some other source than the growth of cereals chiefly for direct profit. This is not an entire delusion, for excepting through the attacks of foot-and-mouth disease the benefits of dairy farming and cattle-feeding have been generally as good as usual. It is, however, a matter for serious reflection on the part of owners of land, as well as the tenantry, that quite irrespective of the price of corn, and where the greatest dependance has been placed under good management of both stock and corn, great tracts both of arable and pasture land also have been abandoned; consequently stock-farming either in cattle-feeding or sheep-feeding has not saved thousands of farmers from ruin, and in various cases more land has by the owners

been laid into permanent pasture, as shown by the statistical returns, often from inability to stock them with sheep to be kept and reared except at a loss. Without reference to the price of corn, which it is now a fashionable and popular prejudice to assert does not pay for growing, and which may be true under the rotations and system of stocking with sheep which has so long been customary, and which has now, through the ruin of farmers, who, although they were good stock managers, yet being men of only moderate means had not money to lose, have been unable to meet the times. The sheep stock system, although it is said to pay the rent, and at the same time manure the land for corn, yet owing to the large capital for investment and extra labour required it has been fatal to the men of moderate means, who have in vain attempted to follow a system which men who possessed capital sufficient to meet losses could continue to meet difficult times and bad seasons.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—The weather in most districts of the kingdom has been lately rather too dry for the Mangold seed to germinate, except that which was sown in April, for the rains which followed the frosts of April vegetated small seeds like Mangolds, Cabbage, Carrots, &c., but the seeds put in later do not appear, and if the season continues a dry one the plant of late-sown Mangolds, Carrots, early Swedes, &c., will not prove a regular one, for it often happens that in hot dry weather the Turnip flea is very destructive, and as far as my experience goes we have no remedy against this mischief, except that of later sowing and waiting for rain. On the other hand it is quite impossible to calculate upon our climate, for we remember various seasons, one of which was 1864, when the Turnip seeds, either of Swedes or common Turnips, did not vegetate in all the early seedings, in consequence of which the Turnip crop was in most districts a failure, and very seriously affected the value of sheep stock as store animals or as ewes for the production of early lambs. The land is now so dry that the seeds sown will not vegetate without rain, but the only thing which can be done is to seed and manure the land as usual and wait for a timely rain. It will be desirable, probably, to wait until the second week of June before seeding; for Swedish Turnips drilled during the first half of the month of June in the southern and south-eastern districts, as well as the home districts, are generally considered the best, as the roots produced in ordinary seasons will maintain their feeding value better when sown at that time. In the northern or north-midland districts, as well as Scotland, the seeds of Swedish Turnips are usually put in about the 20th of May.

Hand Labour.—The men are now busy hoeing of Peas, Beans, &c., for which the weather is very favourable in nearly all parts of the kingdom, for, although some thunderstorms have occurred, there has been no general rain up to the time we are writing (May 20th) since the last week in April. If the weather continues dry the sooner the Broad Clovers and Rye Grasses are cut the better, for then it will not only be likely to make well into good hay, but it will favour the chance of obtaining a good second cutting for hay, and also an opportunity for forcing on a third growth well adapted for ploughing under as manure for the succeeding Wheat crop. Men at intervals may now be employed in turning earth heaps and mixing compost of earth and dung in readiness to be laid out on pasture land as soon as the land is cleared of the hay crop. Horse-hoeing and hand-hoeing of Potatoes, too, should be now going on, for the earliest hoeings are always the most effective, for the weeds in infancy are easily destroyed by hoeing, but not so with those which have obtained a firm root-holding, for in the event of rain succeeding the strong weeds many of them will grow again. The hand-weeding of Wheat, if not yet done, should be continued, and it should be done by women if these can be obtained in farm work; but in various districts they refuse to work, except in haying and harvest, in which case the weeding of Charlock and Poppies, &c., out of the Lent corn should be done by Koldmoo's weed-eradicator, an excellent implement, and offers the only chance in various districts of having the weeding done at all. For where the women refuse to work in the fields there is only the infirm men and lads which are available, and frequently not even these are to be had. If the dry weather prevails it is important that the Clovers should be cut early, for we recollect in 1870 in those cases where the grass was not cut early it was so much diminished by dry weather that it never scarcely paid for cutting on the dry soils and upland pasture districts. The home farmer should now look over his latter sowings of Lent corn, or where the wireworm has thinned the plants, in order that it may be arranged in good time to sow broadcast $1\frac{1}{2}$ cwt. per acre of nitrate of soda. This will produce instantaneous effect if the weather proves ever so dry, and will be sure to prove an economical dressing.

Live Stock.—The cattle and sheep of this country is, according to the statistical returns, greatly reduced in number, but it is especially the case with sheep, so that many farmers may with advantage save their lambs for stock, and save the cost of cake and expensive feeding stuffs generally, and at the autumn find they have sufficient sheep to feed the root crops, &c., of next winter without buying. The rearing of calves, too, is important, for good dairy cows of a good milking kind are, and are likely to continue, scarce if not very dear. The home farmer, too, may rely upon animals of his own breeding and selection if he has used ordinary care, and will be sure to possess better stock of his own rearing than that generally offered in the cattle markets. Mares and foals will now require careful attention, for we do not like the foal to follow the

mare in her work in the field, which she may be expected to take part in when the foal is about a fortnight old. for, irrespective of accidents of various kinds arising, it is important both for the mare and foal that they should not be separated from each other for more than five hours at one time, and if there is more than one foal they do best in company in the boxes while the mare is away at work in the field. We fear that horse-breeding for some years past has not benefited the farmer as it might have been expected to do under more favourable circumstances; yet as a good style of colt well descended of any breed, either for farm work, hunting, or harness work, will fetch double the price of animals bred anyhow; but the latter is too much the fashion, owing to the difficulty of obtaining in various districts entire horses of a good style and character and bred from sound parents. This, together with the careless way the mares for breeding purposes are selected, has brought the business of horse-breeding and rearing into disrepute in various districts. Dairy cows will now be lying out at night on good pastures, yet in hot sunny weather they may be brought into the stalls at about eleven o'clock in the morning, instead of being teased with flies under the trees in the pastures, and remain there until four o'clock in the afternoon, and receive a bait of green fodder, such as Trifolium, Clover, or Vetches, &c., both on coming into the stalls and again before quitting in the evening; and on the generality of pastures, even if plenty of grass is found there, the cows will maintain a better supply of milk and with more cream than when allowed pasture only.

BATH AND WEST OF ENGLAND SOCIETY AND SOUTHERN COUNTIES ASSOCIATION'S SHOW.—This opens at Maidstone on June 2nd, and is expected to be of great magnitude and excellence. The exhibition of implements, machinery, seeds, &c., will be one of the grandest displays ever held in connection with the Society, and very much more extensive than last year's. There are 71 compartments for machinery in motion, against 55 last year; 384 lineal feet of seed shedding, against 279 last year; 4347 lineal feet of ordinary shedding, for agricultural implements only, against 3514 feet last year; 549 lineal feet of hoarding shedding, for cattle foods, artificial manures, &c., against 411 last year; and 850 lineal feet of miscellaneous shedding for carriages and articles of general utility, against 735 last year; whilst 1364 yards of open space have been taken for greenhouses, hay-drying, and other erections, against 892 last year. All the leading agricultural firms are represented in the yard, and many of them have also made entries for the exhibition of field implements in the trial fields. The latter exhibition will possess unusual interest, as it will comprise an exhibition of silos, several having been specially erected, and of the processes of storing and compressing ensilage. The Hop entries number no less than 66, which is 50 more than on the last occasion—viz., at the Tunbridge Wells Show—on which prizes were given in this department. Prizes are given for East Kent, Mid Kent, and Weald of Kent Hops. The bee department will possess special interest, as there are as many as 75 entries of bees, honey, hives, and bee appliances.

OUR LETTER BOX.

Channel Island Cattle (X. W.).—The Channel Island cattle consists of Jerseys, Alderneys, and Guernseys; the former and the latter are the breeds chiefly imported. The number of Alderneys bred on the island is very small, and scarcely over one hundred are imported annually into this country. They may be said to be in most respects a modified form of the Guernsey, having been so much lately influenced by the use of Guernsey bulls, which they very much resemble both in form, colour, and richness of milk. The Jersey is by far the smaller animal, finer in the bone, and neat in its general appearance. The horns are short and thin, being also more curled or crumpled; the face is finer, with a more docile countenance.

REMARKS.

18th.—A very slight shower between 5.30 and 6.30 A.M. This yielded only 0.042 in., and was, according to rule, entered to the 17th. The rest of the day fine and pleasant.
 19th.—Cloudy morning, hazy in afternoon; then clear.
 20th.—Brighter, but still somewhat hazy.
 21st.—Hazy and warmer; fine throughout.
 22nd.—Very fine.
 23rd.—Fine summer day, nearly cloudless throughout.
 24th.—Very fine and hot, the shade temperature reaching 81.3° ; lightning 9 to 11 P.M. in S.W.
 A very fine week, temperature and pressure rather above the average; very little cloud (and therefore great range of temperature), and no rain.—G. J. SYMONS.

ESPALIER APPLE TREES.

NEATNESS, economy of space, full exposure to light and air, facility of culture in training, pruning, shelter, thinning and gathering the fruit, are the chief points of excellence in espaliers; and now that the adoption of improved forms for these useful fruit trees is becoming general, there is little if anything to detract from what it must be owned are not inconsiderable points of merit. It was not always so. Fine as the crop of fruit undoubtedly was upon the old style of espalier; yet its inherent weakness of form invariably led to premature barrenness and decay in the lower branches. The vertical stem with its horizontal branches was so faulty, so clearly opposed to natural laws of growth, that it is surprising it alone should so long have been the only method of training such useful trees, and the fact of its being so may be taken as an illustration of the too common tendency to run in a groove and to take things for granted.

The modern forms which have ousted the faulty horizontal espalier from our gardens are the single cordon and palmette verrier. The cordon consists of just a single stem with the lateral growth kept pruned to form fruiting spurs, and for this purpose is invariably trained diagonally at an angle of 45°, and they are planted 18 inches apart if on dwarfing stocks, and 2 feet or 2 feet 6 inches apart if on free stocks, in order to afford ample space for spur-development, concerning which it may be useful to add one or two hints here. The development of spurs is a process requiring much care and some common sense. We should make the growth of each tree a special study, and never apply a rigid system of close pruning to all alike. Stout free growth is an indication of robust vigour, upon which it is wasteful to put undue restraint, only take especial care to have all spur wood well furnished with fruit buds, and then it matters not if the spurs are an inch or two or a foot or more long. If the latter, so much the better; for, depend upon it, if we are to have a really useful supply of fruit from espaliers we must have something more than the trim pigmy spurs to which the lateral growth is so often and so wrongly restricted. Only remember that long spurs must be kept far enough apart to admit light and air freely to the branch and all round each spur, or barrenness will soon be visible upon parts much shaded, and this is to risk barrenness all over the spurs, a hard winter often proving fatal to the outer parts, especially if the young growth is at all immature in autumn. Many spurs of espaliers suffered severely in the last two severe winters we had, some of the most robust trees losing several inches of every spur, and attention will be called to some striking examples of this spur canker farther on.

Palmette verriers, the other modern form of espalier, are compound forms—partly horizontal and partly vertical—each branch starting from the vertical stem at right angles and turning upwards vertically, so that the end of every branch is on a common level at the same height as the top of the stem. By this excellent method of training we secure an

equal distribution of vigour throughout the tree, and so long as that tree continues healthy the bottom branch is as vigorous and fruitful as the top one. If a shoot is allowed to grow untrained from the end of a horizontal branch, does it not at once turn upwards? Let, then, those who have horizontal espaliers, taking this clear hint from Nature, apply it to the trees, and convert them into palmette verriers, or, to coin a descriptive term, horizontal verticals. In doing this the branches would have to be shortened sufficiently to afford space for the vertical extension, as shown in fig. 100, page 438. It is questionable whether the whole of them should be shortened at once, or whether it would not be better to let the new growth from the two bottom branches have at least a year's start of the others, and thus become sufficiently vigorous to reach the top with or soon after them.

Of the espalier palmette verriers which I planted thirteen years ago fourteen are Apples. They have repeatedly afforded useful matter for cultural hints to readers of the Journal, and are now an interesting study individually and collectively. They form part of a large selection of choice dessert sorts made by Dr. Hogg, and the original intention was to have them on Paradise stocks; but the late Messrs. William and Thomas Osborn strongly advised me to give preference to the free (Crab) stock for espaliers, and experience, gained long previous to the planting, convinced me that I should not do wrong in listening to them. Yet, notwithstanding the vigour imparted by the stocks, three of the trees have succumbed to the attacks of canker. Pine Golden Pippin was the best and most finished specimen of them all. Its growth was remarkably vigorous, the whole of the branches being fully grown and well furnished with spurs in full bearing, the fruit being highly valued for its tender juiciness and delicious flavour; but this valuable tree is dead from canker, which destroyed the bark at the bottom of the stem at the point of union of scion and stock when it was grafted. Ross Nonpareil and Golden Reinette both had the branches so badly cankered that the whole of them are cut back close to the stems, which are so much enfeebled that they will probably have to be destroyed. I particularly regret the loss of Golden Reinette, for it is an old favourite, and its seventeen synonyms are a sure indication of its popularity both in this country and on the continent. The other trees, apart from some canker, may be described as fairly healthy and in full bearing. All of them are now setting an abundant crop of fruit.

Pearson's Plate is perhaps the finest specimen, the tree being 20 feet long and 6 feet 6 inches high. It has canker blotches scattered thinly upon the branches, and the tips of the spurs have all been destroyed by canker caused by the severe weather in the winters of 1879-80. By pruning the cankered parts the damage was got rid of, for the canker did not spread inwards, and the spurs are now apparently healthy and have been very full of blossom. Cox's Orange Pippin has been crowded with blossom, and the fruit is setting so thickly that it will probably require thinning. The tree is in perfect health and is very robust, yet the tips of the spurs have all been pruned for canker, which shows that this troublesome disease is sometimes caused by severe frost. Of many trees which I have planted of this excellent Apple this espalier on the free stock has been the slowest in coming into fruit-bearing. Others on the Paradise, also had from the old Fulham Nursery, bore plenty of excellent fruit long before it; but for early and abundant crops the palm must certainly be given to a dozen trees on Paradise stocks which I had from Messrs. Rivers of Sawbridgeworth. That delicious Apple Reinette Van Mons is well represented here by a tree even more robust than Orange Pippin; but it has suffered equally from spur canker by cold, almost all the spurs having been shortened an inch or two. It has been very full of blossom, and will probably carry a full crop. Melon Apple, of American origin, answers fairly well here and the fruit is much liked, answering perfectly to its description in the

"Fruit Manual:"—Flesh yellowish-white, very tender and crisp, juicy, sweet, and vinous, with a delicate and agreeable perfume. The tree is somewhat peculiar from the comparatively weakly growth of its eastern half, which is also much cankered and deficient in blossom. The western half, on the contrary, is remarkably vigorous, has plenty of blossom, and only a trace of canker upon two or three spurs. I have noticed this peculiarity in some other trees, and may mention a pyramidal Forelle Pear as an example of it.

Cornish Gilliflower is in perfect health, without a trace of canker, and is remarkable for its clean dark bark. It has had enough but not a profusion of blossom, and will probably set a fair crop of fruit. It is an excellent dessert Apple, coming somewhat late into bearing, for which reason there should be several trees of it. Scarlet Nonpareil has many spurs a foot in length, all well furnished with buds. I counted a dozen clusters of blossom on several of them. It has slight traces of canker, but is on the whole a thriving valuable tree. Golden Pippin is a compact little espalier, almost perfect. It has had canker on the spur tips, and there are slight traces of it upon the branches. The blossom has been crowded, and it is setting plenty of fruit.

Pine Apple Russet is a fine vigorous specimen with free

Fig. 100.—Converting espalier into palmette verrier. (See page 437.)

robust growth in branch and spur. It, too, has lost the tips of the spurs from canker, but there is ample promise of an abundant crop of its somewhat unsightly but excellent fruit. Golden Russet may be termed a nice tree, with spurs somewhat thinly disposed but with plenty of blossom. Although a large tree the growth is only of medium vigour, and it has canker blotches. Cockle's Pippin has much canker in the spurs, the tips of which have also suffered; but the stem and branches are healthy. Adams' Pearmain has much spur canker, but it has plenty of blossom. This tree came into full bearing before any of the others, and it has continued to yield full crops of fruit in every favourable season. I do not regard it as a first-class dessert Apple, but it is undoubtedly a most useful one.—EDWARD LUCKHURST.

INDOOR ROSES.

AMONGST these Cheshunt Hybrid is in my opinion nearly equal to Maréchal Niel and Gloire de Dijon for clothing pillars, roofs, or walls in cool houses. A plant budded as a standard in 1881 and planted during the following winter outside a small octagonal conservatory, with the buds just inside, has already covered a large space, and this spring has given us over three hundred of its lovely blooms. This Rose is liked here nearly as much for its scent as for its beauty. Last year, having some good pot plants of Maréchal Niel in flower just when Cheshunt Hybrid was at its best, we trained the shoots of the two together in such a way as to have nearly equal quantities of blooms of each hanging together. Neither of the two lost anything by the arrangement, but each seemed to enhance the beauty of the other. This year there is no room to admit the Maréchal into the space, or the arrangement would have been made again. As much as I like "own root" Roses I cannot advise that system of growing this

variety. With us it grows much faster on either Manetti or Briar than on its own roots.

I have been much interested by the two notes recently on Reine Marie Henriette. I have had a plant of it for two or three years growing outside trained to a wall, and I have not had a single bloom yet, and a neighbour who has grown it much longer than I have has the same experience to record. Only two or three days ago I was conversing with the foreman of a large Rose nursery, and his opinion is that this Rose is both a poor grower and bloomer. I had determined to discard it, but shall now insert a few buds in the old Gloire, of which I have a vigorous young plant on its own roots in a cool greenhouse.

I saw a plant of Gloire de Dijon a few weeks ago which I should think has few equals. Seven years ago it was purchased as an ordinary nursery standard and planted inside a greenhouse 20 feet long, with rafters fully that length. The gardener in charge said he thought the rafters were 25 feet in length, and now the entire roof is a perfect thicket of wood; in fact it is too much crowded, and the plant shows no sign of having reached its limit yet if it had more room. As our indoor climbing Roses go out of flower they are pruned and the soil removed as far down as possible without injuring the roots, and a mixture of loam, manure, and crushed bones applied in place of the soil taken away. By this means the roots are kept from striking downwards, and thus are in a position to make the most of liquid or other manures, which may be given as they require them.—T. A. B.

GERMAN IRISES.

THE broad-leaved Irises (*I. germanica*) form an interesting, beautiful, and useful class of plants for early summer flowering, and for variety and quaint form with exquisite markings are unsurpassed by any other flower of their season—May and early June; and though the flowers are not very persistent they are nevertheless suitable for cutting, for which purpose they vie with Orchids, and are far more valuable from being within the reach of everyone having a few yards of garden ground devoted to flowers. The plants are evergreen, and on that account cheerful at all seasons, their ample broad-flag foliage rendering them conspicuous objects in the borders, and not the least of their merits is that of their succeeding in smoky localities.

The German Iris will grow almost anywhere; but in the shrubbery border it makes slow progress, on account of such positions being too dry and the soil poor from its exhaustion by the roots of trees and shrubs. In the wilderness it grows well if the soil is surface-dressed with manure and kept clear of weeds; whilst on the margin of water it is effective. But to grow the plants well they require a good rich porous soil, without water lodging about the roots, for they are anything but aquatic, and any idea of their being rock plants must be discarded. I mention this because I have seen German Irises perched on rockwork, sunk in a bog, and trying to make a living as best they could in the poor soil and gloom of shrubberies. Such positions cannot show or grow these plants to anything like perfection. They like sun or an open situation, soil loamy, well manured, deeply stirred, and efficiently drained, and then we stand a chance of seeing them in the richness of their foliage and the unsurpassed loveliness of their standards and falls, rich in colour, or distinguished by exquisite markings.

Their place in the herbaceous border, masses a yard across, stand out in May or June as grand ornaments of this now popular department of floral gardening. They grow freely, are very hardy, and increase rapidly, propagation being effected by division in early autumn or early spring. Each crown taken off with a portion of the creeping root-stem will make a plant, planting no deeper than to cover with soil to the base of the leaves or just over the roots. A top-dressing around the clumps of short manure or leaf soil in early winter, pointed in early in spring, and the plants supplied with liquid manure in dry weather, with a mulching of short manure to prevent evaporation, will grow famously through the summer, and form some crowns that in due course afford a harvest of blooms large in size and full in substance. An indifferent bloom is a result of poverty, and may arise from the clumps becoming too crowded with "grass" or the creeping stolons, in which case they should be thinned and a good dressing of rich compost applied over the root-stems between the growths; or if the clumps are too large lift them, divide, and replant in early autumn or spring in well-prepared ground.

The varieties are legion, and as they have been considerably added to of late a selection is appended of those that can hardly fail to please those that have not given this class place in their gardens.

Florentina.—White both in standards and falls, being very free-flowering and scented.

Penelope.—Standards and falls white veined reddish-violet.

Albicans.—Standards and falls white, very fine; the best white.

Donna Maria.—Standard and falls white, tinged lavender, yellow beard.

Madame Chereau.—Standards and falls white, feathered and edged violet; very free-flowering.

L'Innocence.—Standards clear white, falls white veined purple and orange; very fine.

Victorine.—Standards white blotched bluish purple, falls violet veined white; good.

Poiteau.—Standards white tinged lavender, falls dark purple veined white; fine large flower.

Sir Garnet Wolseley.—Standards white flaked purple, falls crimson veined white; superb.

Flavescens.—Standards and falls primrose; large and fine.

Aurea.—Standards and falls deep yellow; superb.

Chénédolé.—Standards deep yellow; falls pale yellow, veined crimson, tinged purple.

Magnet.—Standards yellow, falls purple veined white.

Matthioli.—Standards and falls yellow, veined crimson and white.

Sylvia.—Standards deep yellow, falls velvety crimson veined yellow.

Darius.—Standards chrome yellow, falls purple margined yellow; fine.

Gracchus.—Standards lemon, falls pale yellow veined purple; of compact growth and very free.

Rebecca.—Standards bronze, falls crimson veined white and sa'phur.

Mozart.—Standards bronze, falls purplish; large.

Bossuet.—Standards bronze, falls white veined purple; fine.

Madame Sontag.—Standards lavender, falls violet feathered white.

Marianne.—Standards lavender, falls purple veined white; fine.

Bridesmaid.—Standards lavender, falls white bordered lavender.

Queen of May.—Standards rosy lilac, falls rosy lilac veined yellow.

Cordelia.—Standards rosy lilac, falls purplish crimson margined white; fine.

Pallida dalmatica.—Standards lavender, falls lavender tinted purple.

Madame Paquette.—Standards purplish red, falls rosy purple.

Vietor.—Standards purple-bronze, falls purple.

Lurida.—Standards purplish bronze, falls deep purple; scented.

Atrio-purpurea.—Standards and falls purple; free and early.

Céleste.—Standards and falls blue or deep lavender, orange beard.

Othello.—Standards and falls rich bluish purple; fine.—G. ABBEY.

GRAPE-THINNING.

YOUR correspondent "T. A. B." offers at page 380 a few hints to beginners on Grape-thinning, and so far as to getting a good set I quite agree with him; but as regards his method of thinning, as well as some of his other remarks, I hold a different opinion. To begin with, "T. A. B." does not say what size his bunches are. Perhaps they are like some of the monsters we have seen at the International Shows held at Edinburgh and elsewhere within the last ten years. Supposing the bunches to be of large size they will require some tying, otherwise I consider tying inadvisable if the Grapes are grown for the table, or even for exhibition. Take for example two bunches that are growing side by side. Tie and thin one as recommended by your correspondent, thin the other without tying. When they are ripe cut both, place them either on a fruit dish or on a stand for showing, and mark the difference. I am certain that the one which was tied will fall flat—at least the shoulders will shift, damaging the bloom, which spoils the appearance of a bunch of Grapes, no matter how good it may be in other respects. The untied bunch will lie like a ball if it has been properly thinned.

Thinning Grapes is a very important operation, and requires much experience before it can be satisfactorily accomplished. The operator should know the habit of the bunch to be thinned, such as the length of the pedicels or fruit stalks, the size of berry, &c. When the fruit stalks are long they require less thinning. A very good example is the Black Hamburg and Lady Downe's. The last-named needs more than double the thinning that the former requires. I consider a bunch has been properly thinned if after the berries are fully swelled they retain their places.

Your correspondent next recommends tying a piece of twisted matting round the stem on the lower part of the bunch for moving it as required. I am at a loss to see how the bunch can be moved after it has been tied out first as he advises. A piece of stick 6 or 7 inches long, with one of the ends formed like the letter V, answers the purpose very well. "T. A. B." also says the berries should not touch one another. I fail to see how good Grapes can be grown without the berries touching each other. This he says is a certain way to produce scalding. Scalding, so far as my experience goes, takes place when the berries are stoning. At this stage of growth, if the vine is kept quite cool and airy, there is little danger of scalded berries. I have had a few damaged, owing to having too many varieties growing in one house, otherwise it can be prevented. I have seen them scalded on the very point of the berry. So that proves that the berries touching each other is not the cause as indicated by "T. A. B."—J. J.

GILBERT'S LATE QUEEN BROCCOLI.—I notice in the *Journal of Horticulture* that my new white Broccoli is described as very much like

Cattell's Eclipse. This is an error, inasmuch as the latter has upright foliage and the head is yellow, or approaching to that colour, while the heads of my Late Queen are white and perfectly protected by its incurved foliage.—R. GILBERT.

SPECIALITIES AT READING.

THE spring Exhibition at Reading invariably attracts many visitors to the town, a large proportion being gardeners or others connected with horticulture, and to these Messrs. Sutton & Sons' seed grounds and nursery are equally as great an attraction as the Society's show. There is always one great feature at that time—namely, the Calceolarias; and this year was no exception to the rule, though the hot weather had brought them rather forward. Several houses were filled with healthy, sturdy, well-grown plants, and in one special show house a bank of flowers was formed which for brilliancy of colour and varied tints could not be surpassed. It is surprising the number of shades that have been produced by close attention to crossing and intercrossing the different types; and the markings have also been greatly varied, from the most delicate lacing to the heaviest solid blotches of colour, which stand out boldly upon yellow, cream, and white grounds. In some, too, there is a combination of spots with a regular netting, and in others the light grounds are replaced by a pale rosy crim-on colour, upon which the spots and lacing are strongly marked in a darker shade. The flowers, too, are of good size without being coarse, even, well-proportioned, and full, mostly in compact heads just above the foliage, so that they can be clearly seen. Very prominent amongst them was the handsome yellow self Cloth of Gold, which is wonderfully effective and true. Of the other colours the following will give some idea. Cream grounds with deep crimson spots and veins, rich crimson blotch, crimson-purple dots suffused with the same colour; white grounds with crimson and rose dots; yellow grounds with deep red marbling, crimson netting, bronze netting very handsome, and dashed with maroon; while of selfs, puce, bronze-red, cinuabar, crimson, rose, a bright reddish scarlet, creamy rose, purple and maroon are all represented with many intermediate and indescribable shades.

Gloxinias were not at their best, as it was too early for them, but a few typical varieties were in flower which indicated the value and beauty of the strain. Several very pretty forms have been obtained in which the colouring is very clearly defined, either with a white throat or a white margin round the lobes of the corolla, the colours in the latter case being arranged in crescent-formed blotches. Intensely rich as well as most delicate and soft shades have been secured from white through pink to bright red, crimson, and purple. One group of white-flowered varieties, some of which have lemon-coloured tubes, have been raised from a cross between Avalanche and Boule de Neige, and will undoubtedly become popular, as they are very free, sturdy in habit, requiring no sticks, and the flowers are large, pure, and symmetrical. The erect-flowering type is the favourite, the foliage elegantly recurving, and in many cases quite concealing the pots. The drooping-flowered varieties are useful for baskets or suspending from the roof of a house, but when on a low stage their beauty is lost.

Tuberous and other Begonias of the *B. semperflorens* character, it is well known, have for some time engaged the attention of this firm, and several useful strains have been obtained, not the least of which is Snowflake, a pure white, dwarf, and profuse flowering sort, which is most valuable for decorative purposes. A fine hybrid has also been raised between *B. Schmidtii* and *B. semperflorens rosea*, in which, curiously enough, the pistillate flowers are pink and the staminate flowers white, which have a curious but pleasing appearance on the same plant. In habit this is exactly intermediate between the two parents, and more compact than *B. semperflorens* and stronger than *B. Schmidtii*.

Many features might be enumerated; for instance, the Alpine Auriculas, of which a beautiful strain has been gradually developed, and either for culture in pots or borders many of the seedlings are not inferior to named varieties. The charming *Freesia refracta alba* is also grown in large numbers, its pure white fragrant flowers being much appreciated. Of the outdoor flowers the prominent plants thus early are handsome strains of Wallflowers and Stocks, of which an extremely dwarf type has been raised, forming dense bushes of flowers 8 or 9 inches high and from 1 to 1½ foot in diameter, most varied in colours. Enormous numbers of annuals are tried every year, a great space of ground being devoted to them, and the merits or defects of everything is thoroughly tested before distribution.

SPRING AND EARLY SUMMER-FLOWERING HEATHS.

ONLY a few years ago a collection of greenhouse plants was considered incomplete without a number of Heaths, but unfortunately of recent years they have been almost entirely discarded from private gardens, and at the present time their cultivation is confined to those who grow plants for exhibition. It is probable, however, that they will again occupy a prominent position in gardens, and what plants are more deserving of general cultivation? During the spring and early summer months they are unsurpassed for the decoration of houses that have to be kept gay with a number of flowering plants. The cause of these not being grown is neither the want of skill nor accommodation, but the large and increasing demand upon the gardener for cut

flowers; and to meet this, Heath cultivation has been discontinued and other plants grown which yield a larger return in less time. Judging from the questions asked and answered in the pages of the *Journal*, I believe the tide is rapidly turning in their favour, and information regarding their culture may prove acceptable to many readers.

In commencing their cultivation dwarf bushy young plants should be selected. It is important that the plants be of free growth and healthy, and not kept in small pots long enough to become unduly root-bound. Young plants that have become checked from this cause are a long time before they recover. These plants are generally obtainable in 5-inch pots, the usual trade size, and those should be selected that have become established in that size, for they are much better to start with than if they had been kept the greater part of last year and then wintered without placing them in larger pots. Plants of this description should be grown on in a cool airy greenhouse or in a cold frame, but cold draughts must be avoided, and the pots should stand upon gravel or some moisture-holding material. As soon

Fig. 101.—*Erica speciosa*.

as the plants are secured it must be decided whether they are to flower the following season or be grown on into a larger size before being allowed to flower. When required to flower, their progress towards making specimen plants will be slow compared with those grown for the purpose without flowering.

To grow the plants into a large size as quickly as possible do not keep them in a close confined atmosphere, but give abundance of air when the weather is favourable, and the growths made will be sturdy. As soon as the 5-inch pots are fairly well filled with roots without being overcrowded, which will be the case by the middle of July, they should be transferred into 7-inch pots. Two or three weeks afterwards the roots will be advancing freely in the new soil, and the strongest shoots, or those that are taking the lead, should have their points taken out and then tied outwards, bringing them towards the rim of the pots to form the base of the future specimen. If the plants are healthy these stronger shoots will produce a number of growths. After they have been tied out, if any shoots take the lead they should be pinched to throw the strength of the plant into the weaker shoots, and thus keep the whole well balanced. They must not be stopped after the end of August or early part of September. It may be mentioned that *Erica Cavendishiana*

is naturally of upright growth, and should not be allowed to lead away with two or three strong growths, or the base of the plants will be weak and the future specimen ruined in its early stages. Particular attention is needed with this variety in keeping its shoots well stopped to compel it to form a bushy habit, for if allowed to grow unchecked it will need cutting back; and this is a waste of time when growing the plants into specimens. This variety, which is one of the most beautiful and useful, requires more care in its early stages in this respect than any of the *E. ventricosa* section. The young plants should be kept under cold frame treatment all the season, as they will do better than if stood outside, but free ventilation should be given. During September and October they must be placed in a light airy position in the greenhouse.

The winter treatment is simple when they are given a good position. They must not be started into growth by fire heat. Keep them as quiet and cool as possible until the end of the year, only turning on the heat to exclude frost or to expel damp during dull bad weather. After the middle of January the house they occupy should be kept as near as possible about 45° at night, which will gently excite the plants, and they will commence activity earlier than would be the case if kept cooler, thus giving a longer season's growth the second year. To maintain the temperature named employ fire heat only when absolutely necessary, for nothing is more detrimental to Heaths than dry heat, from whatever source it may be derived.

As soon as the plants have commenced rooting freely in early spring examine them, and if the soil in the 7-inch pots is moderately well filled with roots transfer the plants to pots 2 inches larger. Whether the plants require potting or not depends upon their condition and the growth they made after the second potting the first season. If not sufficiently well advanced they should not be potted, but may be left for a month or two longer. When well rooted they may have a 3-inch shift instead of being potted a second time. This is preferable, and the plants will do better if the grower knows when and how to water them. Heaths in their early stages require liberal root-room, and too many are ruined through being kept in small pots when young, for they lose their lower foliage and become stunted. These plants can, after the second year, be allowed to grow without stopping or potting for flowering the following spring and summer if required, or they can when ready be placed in pots 2 inches larger and grown a third year without flowering if healthy large specimens are desired.

When required to flower, whether the first, second, or third year after they are purchased, they must be grown on an entirely different principle and the wood thoroughly ripened. It is wise when numbers are wanted in flower to divide them into two batches, and grow one lot specially for flowering and the others as specimen plants before allowing them to flower. The winter treatment for both is exactly the same, but in spring the plants to flower should grow without being stopped. When in active growth should have abundance of air, and from the month of August must stand outside to ripen and harden their wood, or better still, occupy frames or a temporary house where they can be protected from heavy rains and storms.

Staking and tying demand more attention than for the winter-flowering varieties, but not when the plants are required for home decoration. At first only a few short stakes are needed to bring the shoots down to the base and to regulate their growth; but when they attain a larger size more stakes will be needed, but the pots should not be crammed full, as is too often the case. The tying should be done with dark thread, which is less visible than matting, and the Heaths when finished have a neat appearance. It may be mentioned that *E. Cavendishiana* is a sturdy grower, and if properly managed will neither want tie or stake, and the *E. ventricosa* family will not require half so much tying or staking as the *E. tricolor* section. Many others are worth growing, including those represented in the figures, which show that the diversity in form is as marked in the varieties as the dissimilarity in colour.

The potting, watering, shading, and general treatment should be exactly the same as that recommended for winter flowering varieties, but in no stage or condition should they be weakened by a close warm atmosphere, which some of those that flower during the winter will enjoy. To achieve the greatest success a cool system of cultivation must be practised, but cold draughts on all occasions must be avoided. It may be mentioned that mildew is the greatest enemy to these plants, and must be watched for carefully during the winter months, and destroyed at once if it appears, as advised on page 298.—W. BARDNEY.

It is strange that these beautiful hardwooded plants are not so generally grown as they deserve to be. We seldom meet

with them in any quantity in private establishments, except when grown for exhibition, for which they are invaluable, comprising as they do nearly all colours and shades, from the purest white in *E. jasminiflora alba* to the rich vermilion scarlet of *E. cerinthioides coronata*, *E. Eweriana superba*, and the bright yellow of *E. Cavendishiana*. These plants ought to be grown in a light airy house—in fact, except in very severe weather the house ought not to be closed. They ought to never have fire heat except to just exclude frost, or to exclude damp during a

Fig. 102.—*Erica cerinthioides*.

continuation of dull autumn weather to prevent mildew, to which they are rather subject, especially the close woolly varieties, such as *E. æmula*. It is a good plan to put most varieties outside, fully exposed to the sun, when they have flowered and have started growing, as it hardens the growth, and they are more able to resist the attack of mildew.

The last potting for the season may be early in August. The pots to be used should be quite clean and carefully drained with clean crocks. Being slow-growing plants they do not require potting very often—a shift every two years after the plant passes a 6-inch pot until it is in one 12 inches or 14 inches in diameter, after which it will not require potting so often, always taking into consideration the variety. If it is free-growing, such as *E. ventricosa* and its varieties, it will require potting oftener than the slow-growing *E. Marnockiana*. When potting, if the plant is in good condition, it is best to give it a good shift, so that a rammer can be used between the soil and the side of the pot, as the soil can then be made firm without injuring the roots. Rammers slightly curved are the best for this purpose (ash if tied to the desired curve when green and well seasoned makes good ones). The use of this curved rammer is to keep the hand away from the plant, as *Ericas* when trained project over the edge of the pot. Two straps about 3 inches wide are very useful when potting large plants to let the ball down into the pot, and if it should not be of the required depth to raise it again. Avoid deep potting—just cover the old soil.

The soil should consist of good, rather hard, fibrous peat,

picked to pieces as large as can be used, the fine being refused, mixed with silver sand and charcoal broken small. Do not use spongy peat, as it retains moisture too long. After they are potted they should be kept rather close and shaded, and have an occasional dewing with the syringe for a week or ten days, and afterwards gradually diminished. I ought also to have said they should not be dry when potted, nor in the opposite condition, but fairly moist, and they will then stand a few days without water if large plants. They may safely be stood outside early in September and remain until October. When *Ericas* are outside at any time, whether fresh-potted or not, always have two empty inverted pots to each plant to lay them down on in case of rain.

Watering is rather a difficult part of the culture of these plants. One man only should attend to them, as he will get to know the ring of each pot and the requirements of each plant. Hard-baked pots (which are best) do not ring so much as soft porous pots, and when in the former less water is required. During summer it is much easier to err by giving too little than too much; they should never be allowed to become very dry at any time. Always give enough water to thoroughly soak the ball, whether the pot is filled once, twice, or thrice. Another point to mention is that the free-growing sorts and plants in good condition will take water oftener than slow-growing sorts, or plants that may not be in good condition. If they are grown in a span-roofed house with east and west aspects they require very little shading, except during the middle of the day; but if

Fig. 103.—*Erica infundibuliformis*.

the aspect is south they will require more shading. In training use as few stakes as possible, taking thread from one stake to another, and looping up a shoot every 2 inches. The stakes should not be put into the soil too far, and should be renewed every year or two at the most, as they are apt to decay at the surface of the soil, and then it is difficult to remove them.—J. GORE.

SYRINGING VINES.

AFTER reading Mr. Waiting's letter on the above subject (page 409) I feel inclined to differ from him in syringing Vines in flower, as I have found from experience that the flowers of Vines are benefited by a gentle syringing, properly applied early on a bright morning, especially in the case of Muscats and other sorts that are apt to exude a superfluous quantity of viscid matter from the stigma. I am of opinion that the cause of Grapes not setting is often the result of the "baking process" that some persons think so necessary. A plant in a pot which can be watered freely if the drainage is good is, I consider, analogous to a Vine in flower in respect to moisture if ventilation is perfect. Perhaps this may seem rather a bold statement to some, and I admit that it is a mode of procedure that requires care, but if we wish for good results close attention must be given to whatever the charge may be. In syringing Vines in flower the chief point is to evaporate the excess of moisture from the flower before stagnation takes place, which would result in the decay of

the pollen grains. Properly applied, and as properly removed by efficient ventilation, it leaves the embryo fruit in a clean fresh condition.

Mr. Waiting evidently has not had much experience with thinning such sorts as Lady Downe's and Alicante, or if he has he would have found it very beneficial to give them a gentle syringing with perfectly clean tepid water to remove the refuse that accumulates in the bunches of these close-berried sorts to prevent rusting.—C., *Dorset*.

GROWING PLANTS IN TURF.

WHERE pots are not easy to be obtained, which is often the case either from being a long distance from a pottery or to the garden expenses being limited, some other method must be adopted. We have a method in practice here which answers admirably for Pelargoniums or almost any other bedding plant. We strike our cuttings in boxes 2 feet long by 15 inches wide, and about 2 inches in depth, where they remain till the middle of February. In the meantime a number of turves are taken off about 3 inches in thickness, 16 inches square, which are each cut into sixteen small squares of 4 inches. A kind of basin is made in the centre of each piece with a knife or the point of a small trowel. The plants when ready are shaken out from the boxes and inserted in the basins and made up with suitable soil. They are then placed in a shallow pit, which has a flow and return pipe round the front, and being on a cold base they require but little water for some time. In about a month from the time of being placed in the pit the plants will be rooted through. From this they are moved and turned about once a fortnight and watered freely, although they never suffer so much from drought as when in pots, especially when small pots are used. In the turf they receive no check at all when planted. There is no further trouble than to place them on the hand-barrows, take them where they may be wanted, and plant them out; besides, there is no collection of pots afterwards, which is an object also when many thousands of plants are bedded out.—J. H.

"VEITCH'S ORCHIDS."

"HAVE you seen Veitch's Orchids?" This for years has been one of the most familiar of interrogatives alike by those who have seen them and been satisfied, also by persons interested in these gorgeous flowers who have not seen the collection in question, and hence like to have the opinions of others who have had the privilege of an inspection. There is something to see that is worth seeing in the famous Chelsea establishment at all times, but never before was such a sight to be seen as now.

A short time ago reference was made in these columns to a new Cattleya house that was then in course of erection by Messrs. Weeks—a span-roofed structure, 135 feet long by 22 feet wide, proportionately lofty, and with a lantern roof. This splendid house is not only completed but occupied, and in such a manner as to strikingly display the resources of the nursery, and to present a spectacle that may fairly be described as unequalled.

Except a gorgeous mass of *Odontoglossum vexillarium* in one corner, the whole of the space is occupied by Cattleyas and *Lælias*; the central stage rising tier above tier, and the side stages all round the house, are filled with these plants. How many hundreds or thousands there are he would be a bold man to guess, and still less could he hope to convey any adequate idea of the effect of the countless flowers as they were seen a few days ago, with countless buds in various stages of development. It can only be stated that the house was, and still is, full of flowers, and each reader must endeavour to realise for himself the richness of the extraordinary display.

As might be expected at the present time, the varieties of *C. Mossiae* are by far the most numerous, and these alone are gorgeous, the dissimilarity in the forms affording gratification for individual tastes, the richer colours and chaste and delicate tints being abundantly represented in plants of different sizes, but the majority handy portable examples, flowering freely in 5 and 6-inch pots. But in addition to these, grand examples and charming varieties of *C. Mendeli* attract, as they ever must do, attention and evoke admiration. These are relieved by several forms of *C. intermedia* and the more imposing *C. gigas*. One specimen of this will soon have nearly thirty flowers expanded, as buds are bursting from the sheaths in all directions, and suspended from the roof a magnificent variety of *C. Acklandiae* is remarkable by its large flowers and richly barred sepals.

Lælias contribute effectively to the beauty of the structure, many examples of the deservedly popular *purpurata* being covered with flowers of great purity of limb and richness of lip. There are many forms of this good Orchid, exhibiting variations both in the size and colours of the flowers, but not one, it may safely be said, that is not worthy of the place it occupies; and, growing on a block, *L. majalis*, with its large and charmingly pencilled lip, was one of the gems of the house.

But apart from the beauty of the flowers, the clean and healthy condition of the plants cannot be overlooked. "The house suits them," remarked the skilful grower modestly. The house is no doubt going to answer admirably the purpose for which it was erected, but the attention the plants receive evidently suits them too. As was remarked by a visitor, a keen-eyed critical Orchid grower, who knows what he is about, and is the reverse of effusive, "A finer lot of plants I never saw; in fact, I cannot see how they could be better." They are in truth about all that the most

exacting could wish, and more than would be expected by many, for numbers of the plants established so firmly, growing so strongly, and flowering so freely, only arrived as imported pieces, rootless and shrivelled, ten months ago.

Another circumstance in connection with this remarkable collection of Cattleyas worth notice is that the whole of the plants have been "thinned out" of the other houses in the nursery without leaving any apparent blanks on the stages. All the other structures are still full—quite full enough—and the specimens must be all the better for the additional breathing space afforded; at least, they have room for sturdy development. In passing from house to house and seeing them all furnished, it is a matter of surprise that they have been capable of holding so many more, and the fact suggests that Orchids are elastic in their nature, yet it is conceivable that the most expert packer would find some difficulty in restoring the plants that now are so imposingly arranged in the great house above noticed to their original places again.

It has been said that all the original houses remain full, and it must be added that there is something to attract in each, not by the splendid condition of these plants alone, but by the beauty of the flowers. There has been no attempt to gather all the flowering specimens together and arrange them in one house, in fact there is no house large enough for this; but the several houses in connection with the agreeable "break" of an artistic fernery form one long promenade of Orchids that astonishes by its extent, diversity, and beauty.

The *Odontoglossums* are an exhibition in themselves, and a most charming one. It is quite impossible to give any idea of the number of spikes which arch over long stages, forming an avenue of elegance such as no other plants could produce. The varieties of *O. Alexandrae*, too, will bear close individual inspection, for the flowers are as fine as can be imagined, and the tints as varied as can be conceived. Numerous other species are also represented. Then there are *Dendrobiums* yet lingering with *Saccolabiums* and *Cypripediums*. Something, in fact, to arrest attention at every step and turn, the whole showing how great is the demand for Orchids since such a supply as this has to be maintained.

Orchid-growing is spreading as the simple requirements of the plants are becoming better understood, and as large and ever-arriving importations enable the popular kinds to be distributed at prices that are the reverse of prohibitive. Many persons fail, no doubt, in establishing a collection by attempting what they cannot achieve. "Cheap batches" at sales are often dear in the end to the inexperienced. These should be left to fanciers and experts, of which there are so many who possess the skill and the means of bringing apparently dead plants to life, and who are willing to watch anxiously and wait patiently for the expansion of some hoped-for novelty, those that are inferior being returned from whence they came. The great majority of persons who desire to grow Orchids will act wisely, and in the long run economically, by procuring thrifty established plants of proved varieties to begin with, as these are easy to manage, and beyond question the most likely to give satisfaction.

So tractable are these plants that, intelligently managed, splendid specimens of the grandest varieties may be grown in a vinery; in fact, it is questionable if finer examples of culture have ever been seen than some that were grown in tubs in a vinery near Leeds, and exhibited by the cultivator, Mr. Temple, a few years ago, and described at the time in this Journal by Mr. John Wills, who ought to know, and does know, good Orchids when he sees them. Those in the great collection under notice are eminently worthy of a visit now by all who are interested in the aristocrats of the floral world.—INSPECTOR.

APPLE TREES FOR ORNAMENTAL PURPOSES.

THIS subject seems to have engaged the attention of planters lately, and certainly some varieties of Apples are very beautiful when in flower, and deserve to be used more than they have been for ornamenting landscapes. They flower a considerable time before the trees generally used for that purpose, and there is besides a chance of obtaining a quantity of fruit from them.

The most beautiful variety I know of when in flower is the Costard, also called Catshead by some, but a very different Apple from the Catshead of the "Fruit Manual." This has flowers of a beautiful deep rose colour, and being a large-flowered variety it has a telling effect at a good distance. It appears to be vigorous-growing when young, and forms a large spreading top. A tree in the gardens here has a top 40 feet in diameter, and in 1881 bore 9 cwt. of fruit, most of which sold for 10s. per cwt. Other varieties useful for their cropping qualities, and also very pretty when in flower, are Golden Noble, Sugarloaf Pippin, Manx Codlin, Wellington, Penny Loaf, Siberian Crab, &c.; also Bess Pool and Court Pendu Plat are very useful, and as these two flower much later than most varieties they have a better chance of escaping the late frosts. The former is fully a fortnight later here this year than most other kinds, and on May 24th was not fully open.—W. H. DIVERS, *Burghley*.

CORNISH HORTICULTURE.

HAVING given on pages 384 and 425 of the Journal a brief *résumé* of exotic plants in connection with Cornish horticulture, it will not, perhaps, be inopportune to make a few statements concerning the important item of vegetable culture as adopted in this county. The abstract principles of gardening probably do not materially differ in one part of the kingdom from another; but various and important elements render certain means most essential to secure particular or special ends. In Cornwall the most important element is unquestionably a climatal one. The south side of

the county is warmed during winter by a marine current that reaches it from the Gulf of Mexico or the Gulf Stream, and at that time the sea is 4° or 5° warmer than the land. The seasons may be said to be some weeks more advanced there than in the north of Italy, but generally agreeing with Naples. This advantage lasts until the end of March. From the early part of May onwards Cornwall loses all its premature gains, if compared with those counties which are as cold or colder in winter but considerably hotter than this county in summer; and it is a well-known fact that trees are often in leaf in the vicinity of London quite two weeks in advance of those in Cornwall, and other vegetation shows a similar precocity. Another distinguishing feature is that we have no summer which brings with it a solar heat equal to that of the midland counties, and to this very circumstance must be assigned the fact that, whereas in the northern counties of England Grapes frequently ripen in the open air, they are here rarely found to form any fruit whatsoever. In short, from its geographical position and physical configuration the westernmost part of Cornwall possesses climatically the advantages and drawbacks of a small island.

Practically speaking, West Cornwall is one vast market garden, the two important crops being Potatoes and Broccoli. Early Potatoes were first sent out from the Penzance district about the year 1820. On investigating the subject I find that the first, or nearly the first, lot which reached London was in 1828, being conveyed thither *via* Falmouth by the Dublin steamers. Even then the quantity exported was exceedingly small. According to Mr. Courtney's "Half a Century of Penzance," "a new business was added about 1838, and it began in this way. Mr. Drupen, the steward of the 'Herald,' and afterwards of the 'Cornwall' steamer, which went from Hayle to Bristol, took up to the latter port some early Broccoli, and they sold so well that he continued his adventure season after season. Of course this did not escape observation, and others tried the experiment, so far succeeding that they carried their trade to London and far into the midland districts of England. The trade in Broccoli and Potatoes gradually increased as facilities for sending them away became more fully developed, and now [1878] above 2000 tons of Broccoli are disposed of yearly." New Potatoes were first sent direct to London about 1838, of course in very small quantity only. Where the rateable value of even the largest growers' produce at that time would only be a few pounds, the crops of some of the present-day growers are worth at least several thousands of pounds.

The ground utilised for Potato and Broccoli growing is rarely without either one crop or the other for more than a week or two during the whole year, and that short interval is usually immediately after the last cutting of Broccoli is made. In order to manure and otherwise prepare for the planting of the Potato crop, the preparation mainly consists in removing the Broccoli stumps, which are usually carted to a heap to form a rich vegetable fertiliser, and in levelling the surface, after which a liberal dressing of stable dung is applied. The time of planting Potatoes is of course governed greatly by several circumstances, but principally by that of the weather. In one or two instances I have known them to be planted in a warm sunny situation in November and to produce fair-sized tubers in February or March, but such cases are indeed few and far between. As a general rule planting commences in February, and is in full swing by the middle of March. Alleys of a spade's width and 2 or 3 inches in depth are formed, the sections of the tubers placed at distances of about 1 foot apart and then covered with soil, the excavation necessary to the latter process forming the next alley. The whole is performed with astonishing rapidity. It may be here remarked that rarely is a tuber placed in the soil whole unless very small. It is generally separated into as many divisions as there are "eyes," varying from two to four, or even five. They thus go such a considerable distance in excess of those planted whole, and if the results of both methods are compared, the former plan will be found by far the most economical and the better of the two. Under favourable circumstances drawing or digging commences in the latter part of May and continues in full force until midsummer. The Potatoes are separated into sizes, the third, or very small-sized ones, being usually given to pigs. The large ones and the middle-sized tubers are packed and sent to market in baskets, locally known as "half-bushel mawns," each containing about twelve gallons and weighing rather over a hundredweight. A Cornish bushel consists of twenty-four gallons, or three times the quantity of an imperial measure. The line of carts, waggons, &c., awaiting at the siding near Penzance to be unloaded during the height of the season often reaches nearly a mile in length. So soon as the Potatoes are dispatched and the haulm cleared off the ground the planting of Broccoli becomes a matter of paramount and immediate importance. The operation is, when possible, done during cloudy, damp, and even very wet weather. When the ground is very dry, and rain a remote contingency, the roots of the young plants are bodily immersed in a pan of water immediately before being placed in the soil. Broccoli are obtainable nearly the whole of the year round.

The culture of other vegetables has of late years occupied the attention of market growers to a very considerable extent, Radish and Asparagus more especially. Of these two the last-named is the more profitable, although a few years since handsome returns were frequently made for Radishes. At Scilly the crop is still, I understand, a fairly lucrative one. Good crops of both vegetables in the sandy soil of many parts of Cornwall can scarcely be surprising. One winter, a few years ago, Parsley fetched the most unusual sum of 2s. 6d. and more per pound, and those who had plenty naturally made a good deal of money out of it. The following spring more seed was sold and sown than was ever known before; but the produce brought little or no money, and the experiment was therefore an entire failure. Crops of vegetables sometimes realise

large and altogether unexpected returns, but the supply almost invariably exceeds the demand of the succeeding season. Onions and early produce of Dwarf French Beans are at times very saleable, as are also a few of the more popular herbs. Cucumbers, when forced early, have realised very large sums of money, two or three market gardeners in the district of Penzance having each several specially constructed houses for their sole culture.

The importance attached to fruit-culture with a commercial aim has, until the last few years, been of a very secondary consideration. Orchards were, and are still to a lamentable degree, almost entirely neglected, little or no training or pruning being done. There are scores of acres of orchard ground which undoubtedly prove a source of income to their owners if but a small amount of culture were expended on them. A number of the trees are covered with moss and lichen, and many more never, under the most favourable circumstances, produce fruit—in short, as a whole the Cornish orchards need a thorough and complete renovation. Several exceptions to this general rule could, however, be named. In the more highly cultivated orchards Raspberries are almost invariably grown, and in a most satisfactory manner both culturally and commercially. One grower—Mr. W. Thomas, Gulval—alone sends to various markets several hundredweights daily throughout the season. They are packed in a heap in large tubs. This fruit, as well as Gooseberries and Currants, are pretty certain to yield a fairly good crop. It is quite different with the Apple, which, although it generally flowers freely and well enough, the early spring winds do a great amount of damage, and short crops are the rule rather than the exception. Much of this mischief, I contend, would be obviated if a certain few precautions were taken. Strawberries have for a number of years been grown more or less extensively, and are generally a paying crop, particularly the very early and the extra late kinds. Those known as "wall fruits," such as Peaches and Nectarines, are scarcely ever produce anything. As I have previously stated, Grapes cannot be brought to bear in the open air in Cornwall, although I have tasted fruit grown against cottages in North Norfolk. It is scarcely necessary for me to detail the various cultural methods employed for each individual crop.—WILLIAM ROBERTS.

VINES BLEEDING.

"JUSTITIA" must read my notes again, and then his own. His belief, doubts, statements and incredulity, and threat of a visit puzzle me. If my short notes on the above to "Journeyman" puzzle him, surely no visit would enlighten him. The Vines were fruited last year, and formed a perfect chain from the top to the bottom. Scores of people saw them. Those that bled this spring and cast the fruit surely cannot be expected to overlap each other this season.

I still maintain that water is the chief cause of bleeding, whether the roots are deep or not. Debility in the Vines no doubt assists, but is not the cause. Let "Justitia" water a Vine when bleeding, and see the result.

Light has no doubt very much to do with the success of the Vine on a back wall. One of mine had eleven bunches on one side next the south-east end. The front Vines are 5 feet apart, pruned on the short-spur principle. Those on the back wall were planted between them, and young Vines are now planted between the front ones.

I give three years' average of bunches from four Vines on the front. One Black Hamburg, 35, 51, and 36; two improved ditto, 43, 42, and 28; three Mrs. Pince, 36, 22, and 26; four Muscat Hamburg, 28, 39, and 22.

"Justitia" no doubt was staggered by the number and weight of the bunches. I computed the weight; as we do not use either scale or measure here no doubt I might err a little. I have been lifting the outside roots, taking out two old rods, and carrying up new canes, and this may account for the variation, but I always manage to secure a very good crop.—J. E. WAITING, *Grange-over-Sands*.

ROYAL HORTICULTURAL SOCIETY.—Messrs. Kelway & Son, Langport, propose making a large display of DOUBLE AND SINGLE PYRETHRUMS AND PÆONIES at the meeting at South Kensington on June 10th, remaining on view for a fortnight.

—TEMPERATURES.—Could any of the readers of your valuable paper kindly give me the mild night temperatures of the following houses should be kept at during each month of the year? Specimen stove, East Indian house (Orchid), Dendrobium house, Cattleya house, Odontoglossum house, propagating house, and Eucharis house.—G. G.

—In our report of the Floral Committee of the Royal Horticultural Society on page 430 Mr. Knox was credited with exhibiting Pansies. The flowers in question were exhibited by Mrs. Owen Knox,

and well merited the vote of thanks that was accorded for them, as they were extremely beautiful and much admired.

— THE first Show of the BEDFORDSHIRE HORTICULTURAL SOCIETY is announced to be held at Bedford on July 16th. As we have not received a schedule we are unable to refer to the prizes, but we are informed that "those for the Roses are open to all England."

— WE are informed that the VINES AT LONGLEAT, which became celebrated under the superintendence of Mr. William Taylor, are not likely to degenerate under the charge of his successor, Mr. Pratt, but, on the contrary, the crop this year is of unusual promise, the Vines being laden with splendid bunches, quite equal if not superior to the fine examples of previous years.

— MR. STEPHEN CASTLE writes to us as follows on SINGLE DAHLIA SCARLET GEM—"Among my small collection I had a few of the above, and though only in 60-size pots the plants showed flower buds, so I planted two in a cool vinery. A gem it is, and I believe for culture in pots is likely to be very useful. I cannot speak too highly of this variety for its early flowering and splendid colour, and should imagine there would be no difficulty in having a blaze of bloom in May."

— THE same correspondent also observes:—"I regret to say that from six dozen pyramid Pears which were a wealth of bloom we shall not have a Pear, the frost coming just when the trees were in their beauty. We had 10° of frost one morning, which completely crippled them. Apples also on the north-west sides of trees are bare of fruit; Cherries also are very thin; Gooseberries very plentiful."

— DR. PATERSON, Bridge of Allan, N.B., sends us flowers of an extremely fine CYPRIPEDIUM CAUDATUM, with petals 2 feet 3 inches long, one of the best we have seen. A wonderful branching spike of Aerides Fieldingi was also sent, bearing a large number of highly coloured flowers. The main branch was 1 foot 9 inches long, another 1 foot, and a third 9 inches.

— THE LATE MR. JAMES DAVENPORT.—We regret to announce the death, on the 28th ult., of Mr. James Davenport of Droylsden, one of the oldest of the Lancashire artisan botanists. In another month he would have attained his eighty-fifth birthday. For about forty years he had been connected with the Manchester Botanists' Association, of which he was the oldest member. A correspondent who was a pupil and friend of Mr. Davenport informs us that "he worked for upwards of three-quarters of a century, spent it in the cause of horticulture, having been apprenticed at a very early age with a firm of nurserymen at Liverpool. In his younger days he was most enthusiastic as a Pine and Cucumber grower. Thus has passed away at an honourable age one of the best gardeners of his day, a thorough botanist, and one of the chief originators of the popularity of Fern-growing in this country, he being known in the Manchester district as the 'father of Fern-growers.'—J. W. M."

— WE have received the schedule of prizes of the LOUTH FLOWER SHOW, which is to be held in the grounds of Joseph Bennett, Esq., Louth, Lincolnshire, on July 17th and 18th; and observe that in the open classes for Roses that three prizes—namely, £10 10s., £3 3s., and £2 2s., are offered for forty-eight varieties, but subject to the conditions that "unless there are five competitors no second or third prize will be given, and unless there are seven competitors no third prize will be given." The schedule contains 168 classes. Poultry and bee shows will be held in connection with the Exhibition.

— FRUIT PROSPECTS IN CO. MEATH.—"J. P." writes:—"Although the winter has been exceptionally warm we have a very late spring, consequently the fruit should have a good chance. Apple trees are just blooming; the flower is very healthy, strong, and plentiful. Pears are not quite so good, but a fair sprinkling has set on most kinds. Plums are plentiful. Bush fruits are abundant, especially Gooseberries. Strawberries are now white with flower. Peaches, Nectarines, and Apricots are out of the question here; however, we have good crops inside. With a continuation of fine weather I trust we shall have a good supply."

— MESSRS. ANT. ROOZEN & SON, Overveen, Haarlem, send us some extremely handsome blooms of double ANEMONE CORONARIA, representing numerous distinct and prettily coloured varieties. A few of the best are the following:—Beauty, white, with mauve streaks;

Mary Stuart, scarlet and white, purple centre; Reine des Beautés, white, with red streaks; Dame d'Honneur, white, with red streaks, very pretty; Jeannette, bright scarlet, very rich; President Grant, scarlet, white centre; Lord High Admiral, scarlet, white centre; La Delicatess, white or yellowish, with a few streaks; Le Vesuve, rich scarlet, very bright, lighter centre; Prince Oscar, blue-mauve, darker centre; Duchesse de Lorraine, rosy crimson, centre white; Duke of Buccleugh, bright red, white centre; Columbine, white, streaked with pink; La Fidèle, white, with blue streaks; L'Incomparable Rubens, deep crimson, white centre; Rosette, white, with pink centre; and Goethe, white and rose. All were very pretty, and the contrast of colours most pleasing.

— THE finest BROMPTON STOCKS that we have seen for many years were exhibited by Messrs. Veitch & Sons at South Kensington last week. They were arranged in a group of cut flowers in which bunches of Aquilegias, Pyrethrums, &c., were prominent, and in recognition of their merit and the effectiveness of the arrangement a silver Banksian medal was awarded. Though all the flowers were superior, the Stocks were especially commanding by the massiveness of the spikes and the large double crimson-scarlet flowers. Brompton Stocks appear to have been too much neglected of late, and it is gratifying to see that the old strain, plants of which were the pride of so many gardens thirty years ago, is not extinct. This variety has no superior, if an equal, in the family to which it belongs. It is one of the finest ornaments for gardens during the early summer months, and well-grown plants in pots are also splendid for conservatory decoration earlier in the season.

— THE Postmaster-General has issued instructions for packing articles for transmission by parcel post. The following refers to PACKING FRUIT—"It is indispensable that fruit, especially as the season advances, should be packed securely in tin boxes with tightly fitting lid, and in such a manner that the juice may not exude. Much damage is done to the contents of mails from neglect of this precaution, and much disappointment to both the senders and recipients of fruit parcels is occasioned with a little care and forethought would prevent." He further reminds the public on packing generally that the main object of careful packing is to prevent the article packed moving to and fro in its box or other receptacle during transit.

— FROM a series of remarkable articles by Professor Leone Levi in the "Leisure Hour," on the income and expenditure of the British people on the CONSUMPTION OF POTATOES. "Next to bread, the Potato is most largely used as farinaceous food, especially in Ireland. The home growth of Potatoes was estimated by Sir James Caird at 111,000,000 cwt. According to the agricultural statistics for 1880, the number of acres under cultivation in the United Kingdom was 1,380,578. Estimating the produce at 3 tons per acre, the total produce would be 82,835,000 cwt., and at 6s. per cwt., the cost would be £24,850,000. Add 9,750,000 cwt. imported, at an average price of 5-84s. per cwt., value £2,847,000, we have a total quantity of 10,000,000,000 lbs. of the value of £27,697,000, and with 20 per cent. for distribution, £33,238,000."

— GARDENING APPOINTMENT.—We are informed that Mr. Divers, the experienced foreman at Burghley Gardens, Stamford, has been appointed gardener and estate superintendent to J. J. Hopewood, Esq., Ketton Hall, Rutlandshire, whose garden is reputed to contain the finest Peach houses and the best collection of Peaches in England.

— A FASCIATED HYACINTH—A CHALLENGE.—A sheet of printed correspondence has been sent us on the subject of exhibiting Hyacinths with double spikes, and which has resulted in Messrs. Wm. Cutbush and Son of Highgate issuing a challenge to Messrs. Dickson, Brown, and Tait of Manchester to show twenty-four varieties of Hyacinths, single spikes, at Manchester any time between the 15th and 25th of March, 1885, the loser to pay in the name of the winner the sum of £10 10s. to the funds of the Gardeners' Royal Benevolent Institution. It appears that Messrs. Cutbush staged Hyacinths with twin spikes, "not for competition," at Manchester on March 18th of the present year, and on a protest being lodged the Council of the Manchester Royal Botanical Society passed a resolution very much regretting the occurrence, and inviting an explanation. The "explanation" tendered was in the form of letters from Messrs. Veitch, Williams, and Baines, which sustained Messrs. Cutbush in what is undoubtedly a general custom in non-competitive groups, and in which the exhibitor has the right to stage plants with twin or fasciated spikes when his bulbs produce them. If such spikes are objected to it is for the framers of schedules to

specify this, as has been the case in the schedule of the Royal Botanic Society of London. The challenge in question remains open for acceptance till the 30th inst.

— **THE INNER TEMPLE GARDENS.**—By permission of the Benchers the Inner Temple Gardens on the Thames Embankment were opened to the public on Monday last, and will continue open during the months of June, July, and August, from six to nine o'clock every evening. This is a great boon to dwellers in the densely crowded district adjacent, and thousands of children cannot fail to be benefited by the advantage accorded of disporting themselves on the spacious lawn, to which, Mr. Newton has informed us, they do little or no damage.

— **FOOD PLANTS INJURED BY INSECTS.**—In connection with a flower show to be held at Frome on August 4th, there will be a novel competition, being a class for the best collection of food plants injured by insects, accompanied by specimens of the insects injuring them. Each of the collections must be accompanied by a short and simply written account of the attacks represented, and what were done to get rid of the insects, and whether successful or not. No scientific descriptions are needed, but only a simple statement of facts. The prizes offered are £3, £2, and £1, and are given by Miss E. A. Ormerod, F.M.S., Consulting Entomologist to the Royal Agricultural Society of England. They are open to the whole of the United Kingdom. As the entrance fee is only 2s., and as the competition is the first of the kind ever held, this ought to be a most interesting feature of the flower show. The Hon. Secretary is Mr. Henry F. Moore, *Frome*.

— **THE annual Exhibition of the ROYAL NATIONAL TULIP SOCIETY** was held in conjunction with the horticultural Show at the Botanic Gardens, Old Trafford, on Saturday last, and a highly interesting display was provided; the number of exhibitors and general quality of the Tulips staged being fully equal to preceding shows. Manchester people are accustomed to and welcome these shows; but in the south of England such an exhibition would now be quite a novelty, for comparatively few are acquainted with the beauty of florists' Tulips. The principal class was for twelve dissimilar varieties, two feathered and two flamed in each section. In this the Rev. F. D. Horner won chief honours with beautiful fresh blooms of Mrs. Cooper, Industry, Garibaldi, Queen Mary, Duchess of Sutherland, Rose Celestial, Dr. Hardy, Annie McGregor, Sovereign, Sir J. Paxton, and Talisman. Closely following were Messrs. J. Thurston, J. Knowles, J. Morris, and D. Woolley. In the classes for smaller numbers of varieties the competition was very keen but it was particularly so for single specimens, some hundreds of blooms being staged, the above-named exhibitors, together with Messrs. Baker, Barlow, Prescott, and Woolley, taking the leading prizes.

— **A NOVEL EXHIBITION** was opened at the St. James's Hall, Manchester, last Thursday, and though devoid of the interest attaching to competitive exhibits, it was remarkable for the excellent taste displayed in the arrangement. A large number of Rhododendrons, Azaleas, Roses, Spiræas, and similar plants had been purchased for the occasion, and under the superintendence of Mr. J. F. Johnson these were disposed in bold handsome groups which, in the spacious hall above mentioned, had a most beautiful effect. Mr. Johnson deserves much praise for the skilful manner in which the Show was arranged, and proved conclusively that there is yet much room for improving the effectiveness of horticultural exhibitions generally. The Rhododendrons were superbly flowered, the colours bright and varied, and the Azaleas were not only brilliant in colours, but filled the hall with their powerful fragrance.

— **MESSRS. CASSELL & Co**, Ludgate Hill, send us samples of the current issues of several of their serial works, including the following:—Part 46 of "Paxton's Flower Garden," which gives coloured plates of *Oncidium cucullatum*, a very poor variety and dull-coloured, and *Azalea amœna*, which is also rather unsatisfactory in colour. Part 2 of "Popular Gardening" has a continuation of "Roses and Rose Culture," "Garden Walks and Roads," "The Life History of Plants." Chapters are also given on the "Flower Garden," "Kitchen Garden," "Garden Pots and Potting," and "Florists' Flowers." Part 64 of "Familiar Garden Flowers" describes the Tulip and *Saxifraga peltata*; Part 37 of "Familiar Wild Flowers" being devoted to the Teasel, the tuberous Moschatel, the style of both the latter being similar to that in preceding parts. Part 5 of the "Encyclopædic Dictionary" is continued in the same admirable manner as we have previously commended, and Part 2 of the "Book of

Health" contains a continuation of the description of fruit and vegetable foods.

— **AN AUSTRALIAN VINEYARD.**—Among Australian vineyards that of Mr. John Wyndham, Dalwood, New South Wales, occupies a prominent place. The Vines cover an area of 70 acres, the quantities of Grapes produced annually varying according to season. The vintage of 1883 exceeded 45,000 gallons, after the loss of nearly half the crop by hail, &c. The vineyard covers an area of 70 acres. The cost of cultivation per acre is from £18 to £20, the whole vineyard being kept at all times in perfect order. The character of the wines ranges from light to medium full-bodied, strength from 20 per cent. to 24 per cent. natural proof spirit, the bulk being 21 per cent. natural proof spirit. The wines are not fortified. The soil is a red sandy loam, generally of great depth, with a substratum of ironstone gravel; then a rich marl clay, intermixed with small globules of lime. The Vines are staked and trained on wire espalier fashion. The Vines were first planted by the late George Wyndham, the father of the present proprietor. After the new plantation began to bear fruit the old Vines were taken up. The industry has been established at Dalwood for more than fifty years, and nearly the whole life of the present proprietor has been devoted to its development and perfecting. The vineyard is kept in the highest possible state of cultivation, and all Vine and wine refuse is regularly returned to the soil in a systematic manner. The quantity of wine in stock is over 71,000 gallons, and the quantity produced since 1876 was over 276,000 gallons.

PRUNING AND SIZE OF ROSES.

THE mistake "J. A. W." makes about big Roses is much the same as "A. C." and "W. C. T." make about pruning. There is no laying down a general law. I do not think a beautiful Rose is made any worse by being made larger by good care and treatment. Her Majesty is large, but it is by no means coarse; it is like an improved form of a very good old Rose, Charles Lawson and Baronne Prevost. The old Blairii, again, is not easily surpassed, or the Cabbage and Moss. I would not think of putting Her Majesty into a lady's bouquet, but we do not grow our Roses for ladies' bouquets only. There are plenty of smaller buds and flowers from the side shoots for that purpose; but I fear if "J. A. W." were to try to persuade exhibitors to put them up in their stands the verdict of the judges would not be in their favour, and I have had more than usual share of experience, having judged perhaps about 500 times, more or less. Beunett's seedling is certainly a wonderful development of size, though it cannot be called graceful any more than a big Dahlia or a large blossom of Hollyhock.

When judging at Manchester the first time A. K. Williams was exhibited, I and my co-partners had finished the nurserymen's classes before the amateurs' had been judged; so my friend "D." of Deal said to Mr. Cheales and me, "Go and do the new Roses." At once I said, "There, that's the best Rose I have seen as a new one since I was so taken by a staud at Birmingham of Dupuy Jamain." It was large. My verdict was wonderfully true, as last year it was at the top of the tree or Rose list, equal with the old champion Marie Baumanu. Now, there is no Rose that opens every bud, great or small, better, and no Rose better for the front of a house. I cannot praise it too much for forcing either, and it strikes like a weed; so will almost any Rose if persons would get out of the absurd plan of trying to strike them by sticking long bits in the ground under a north wall. Every Rose will strike if strong young shoots just after the blooms have been cut are put into pans in a warm propagating house. No one, I believe, hardly knows that bottles of water in a stove will strike plants that refuse to strike in any other way, Lapagerias, for instance, and many other plants. This makes me somewhat digress, but such criticisms, or we will say remarks, as those of "J. A. W., Alderminster," will not, I expect, in any way alter the opinion of rosarians about big Roses. The way to appreciate them is to put them in shallow glasses, but sufficiently tall to hold each a single specimen, or in a stand at a show.—C. P. P.

AURICULAS IN SCOTLAND.

DURING the blooming season just closing I have had the pleasure of seeing a number of collections in Scotland, from those of two or three thousand each at Raploch near Stirling, and Bankhead near Duns, down to such as my own of about as many hundreds. My impression is that, over all, the bloom was less simultaneous than we generally have it, the trusses on the whole smaller, and, while the quality was at least an average one, that there was in not a few varieties a greater tendency to "sport" than usual. I noticed a most curious freak of this kind in the case of St. Augustine at Raploch, where the diversity in the pips of one truss was unusually singular. Among others General Neil, uncommonly good now and then, has varied greatly, and Imperator was everywhere unrecognisable.

The friends of the veteran Mr. Meiklejohn, now close on eighty-seven years of age, will be glad to learn that he has rallied surprisingly from the severe bronchial attack of last autumn. I am reminded of a call I then made while he was nearly at the worst. A plant of Acme then in bloom had to be brought in, and I verily believe the sight of it did him more good than the previous medical potion.

In noticing such extensive collections the mere mention of any outstanding items must suffice. I remember, then, at Raploch the bloom of one plant of Mrs. Sturrock as certainly the most refined I have seen, the best Duchess of Oldenburgh, excellent examples of Campbell's Confidence and Trail's Anna, and the only cases I met of Page's Champion and Ashton's Bonnie Lass. Mr. Meiklejohn's own green-edge, J. B. Kerr, I missed in bloom this year, but his grey edge, John Morris, was very fine. It bears itself very much in the style of Acme, and will yet be more heard of. A second truss on a plant of Prince of Greens was the best I have seen. The same variety was promising to be as fine in the collection of Mr. Jeffrey at Falkirk. With these two exceptions I have never met the Prince in very attractive form. Mr. Jeffrey had also Lord of Lorne of very fine quality, indeed a large proportion of his flowers were so. His Headly's Petronella was equal in all but size of truss to a very fine example of it in the capital healthy stock of Mr. Menzies at Bankhead. Along with all the commoner and many of the rarer varieties, I there saw for the first time Duke of Argyle. Charles Jas. Perry and Pohlman's Mazzini were both in fine form, as were also Smith's Ne Plus Ultra and Lightbody's Countess of Dunmore. I could not manage to run to Dundee, where Mr. Morris has had, as he writes me, a display rather irregular in time, but of fine quality. I welcome as a fine addition to the class of selfs, which I consider still the most defective in many points, a plant of Low's Mazzini he kindly sent me, and which, though received late, sent up three pips. From what it showed I shall look forward with interest to its flowering next year. One may be unduly biassed in such judgment and his vision unintentionally impaired by partiality, but I fancy—and I do not speak without sanction—that I came across no Acme, John Waterston, Countess of Wilton, Glory, Lycurgus, or Pizarro that surpassed my own.

Somewhat astounded at this blast of my own trumpet, I pass on to answer a question often put to me by those who so much admired my own flowers—"Are they difficult to manage?" I write in the hope that many more of my brother amateurs will be induced to take stage Auriculas in hand, and I believe they would do so were the delusion fairly dispelled under which I laboured when with no little trepidation I some years ago began with a dozen varieties. Let me state a few facts. I know them grown and thriving in the closer quarters of towns, and in the free pure air of the country, in all sorts of houses, except where there is heat, in all sorts of frames, and in some rickety structures in which I would almost hesitate to try any plant. Some growers use carefully prepared composts; one large collection is grown with but little addition in the ordinary garden soil. I find them in pots glazed and unglazed, and of widely differing sizes. In some cases the lights are almost never, except in the most inclement weather, closed on them; in the case of one of the best and largest collections I know circumstances render it necessary to keep the lights constantly down, except when the plants are being tended, air being admitted from below and at the sides. What other flower is so accommodating? I now repeat what I replied to all inquirers, that very few flowers give me so little concern as to their management. And so to all who may be induced to join the ranks I would say: Begin at once with good sorts. You will succeed with them or with none; and many of the varieties that have been recommended in the Journal can be had as cheap or nearly so as inferior varieties.

I cannot understand, except on the explanation of wanton waste, how such varieties as Arabella, for instance, which I have never had or seen worth one-third the money, or Trail's Beauty, both of which, as a friend says, "grow like weeds," should continue to command the price they do. Another friend whom I consulted, and to whom I am indebted for a helping hand, wrote me, "For some sorts you may whistle as sailors do for wind, and with much the same result." But by what is known as paying for your whistle and by welcome friendly aid, it is wonderful how one gets one. Of course, for some of the later additions that we read of at the great southern tournaments we must just make up our minds to long, and sigh, and wait.

Suitable soils have been often described in these pages. I place most reliance on a little good old turf. With the soil moderately damp crock well and pot firmly, they like that. Admit air freely at all suitable times. Do not at any season expose them to strong sunshine. I have now concluded to keep my frames always facing north. Keep the surface of the soil always clean and open, and never allow the leaves to flag; give water all the year round sufficient to prevent that. Do not take off offsets till they are pretty strong and rooted. Above all, avoid that most objectionable phase of the period of "resting," falsely so termed, where, as I have seen it carried out to the full, the poor Auricula is pitted against grass and plantation as if to decide the question of the survival of the fittest. Yet even to such unequal odds the ill-used flower will long refuse to succumb. Pity that it should ever again reward its owner's neglect with a sight of its beautiful face! Try them on the lines indicated, and your experience will, I hope, be mine in a returning display of such attractiveness that the ejaculations of admiring visitors would seem enough to make the sweet flowers droop their lovely modest heads. But, a last caution. If you have already enough on hand leave them alone. A growing acquaintance with these winsome insinuating flowers will be certain to result in a growing drain on your time and attention, to the detriment if not the dismissal of some of your present favourites.—A NORTHERN AMATEUR.

LESS AIR FOR PEACHES.

SOME months ago Mr. McIndoe of Hutton Hall, I think, contributed some very interesting notes on growing Melons without air, and promised

your readers further notes on growing Peaches with less air. I have not noticed that this promise has been fulfilled, and I scarcely think it can have escaped my notice. He will now have the advantage of another season's observations, and I hope he will favour the readers of the Journal with any information on this point, as I think it is moving in the right direction.—R. I.

DOUBLE NARCISSI.

PERSONALLY I am not so partial to double as to single Daffodils, yet there is much of value and interest in them, so much of the latter that I cannot allow this season to pass without penning a few remarks upon them. I have been unusually interested in the flowers as well as in the numerous notes in the horticultural press; and while gladly coinciding with the larger portion of what has been written, yet there have been certain instances in which, judging solely from my own observations, I could not agree with the writers. This is particularly so with regard to the supposed origin or parents of some of the varieties now cultivated. The few remarks made herewith are summarised after examining many flowers of many forms.

Beginning with the trumpet section, with the almost endless forms included therein, all are in my opinion of one common origin, which for convenience sake we may name *N. Pseudo-Narcissus*, proceeding in one direction from the typical size to the much smaller *minimus*; while another line diverges from the type till we reach the larger form called *bicolor Emperor*, which, as far as I know, is the largest of all single Daffodils. In this trumpet series there are several duplicated forms, but all can be arranged under two groups—viz., 1, Double *Pseudo-Narcissus*. 2, *Telamonius* double, each having a very varying series of duplicated forms, which becomes extremely puzzling the more they are studied, so that without any difficulty they might be thrown together. In the first group may be included the double forms of the true wild Daffodil and *Capax* or *Eystettensis*, commonly known as "Queen Anne's Daffodil." The latter I believe to be a double form of one of the sulphur-coloured varieties of *N. Pseudo-Narcissus*, as it is almost self-coloured, with a stellate imbricated arrangement of the segments, very similar to that in a very rare double form of *N. Pseudo-narcissus*, and there is little or no perfume, such as is so strikingly emitted from the duplex forms of *Telamonius*; the leaves, bulb, and habit evidently favour what is here given as its probable origin. Then there are the double forms of the common wild Daffodil, of which I have three—1, with the perianth quite perfect, but sometimes there are more than six divisions, and the trumpet is intact, but partially filled with petaloid segments, all of the same colour as the tube; this was collected in Devonshire, and occurred with some of the single form amongst a batch of the double *Telamonius*, and its origin is not at all difficult to understand, for many of the petaloid segments of double *Telamonius* are polleniferous, and it is quite likely that flowers of the single form were impregnated with such pollen, and the progeny would most likely by that means become semi-double. 2, Perianth quite perfect as in the last; trumpet more crowded and shortened ultimately splitting up, with the segments freely fringed; usually these are all of the same deep yellow colour, but sometimes there are a few light-coloured segments intermingled. This is evidently a still further development from the last, and was collected from the same batch. 3, Perianth and corona interblended, having the stellate-imbricated arrangement of *Capax*, with the paler and deeper-coloured segments regularly alternated, forming a most charming contrast, rendering it in my opinion the prettiest double Daffodil in existence; the leaves are very much broader and altogether larger than the typical form. This form, too, is almost scentless. This form is, I think, figured in Burbridge's "Monograph," but the edges of the segments as there shown are fringed, whereas those of the flowers I have are not. I must not forget to mention the double form of the variety *cernuus*, which is very double and rose-like in form, and, unfortunately, far too rarely seen in our gardens.

The *Telamonius* section of duplex forms are, I fancy, the result of a cross between double forms of *N. incomparabilis* and some of the larger single-flowered varieties of *Pseudo-Narcissus*. I take this view chiefly on account of the strong perfume you get in this section; whereas, as far as I know, the single forms of trumpets have at most but a very slight scent, besides the perfume is much like that of the peerless Daffodils. I am inclined to ask where this perfume comes from. Is it possible that in the multiplication of parts—assuming this to have had a common origin—there would also be a development of perfume so striking as is evidenced in the case of these Daffodils? If so, why is there not a proportionate increase of scent in the double forms of *N. Pseudo-Narcissus* proper? I fail to detect it if there is. Taking this view of the matter, the question arises, Which of the double forms were first cultivated in our gardens or those of continental Europe, the peerless or the trumpets? and this is a difficult matter to be certain about. We should be materially assisted if authentic information could be obtained from continental sources, as I am of opinion that the double forms of *N. incomparabilis* are of south or middle European origin. There is a great variation in size and form of this series of double Daffodils, and I include therein what one may call the typical double *Telamonius*, *grandiplenus*, and *lobularis plenus*. The former is, I think, the Van Sion of continental dealers, and is very variable. Some of the flowers are crowded with segments, evidently the result of extra doubling of the corona, while in others the number of segments is materially lessened, and they are disposed in a stellate-imbricated manner similar to the form of *N. Pseudo-Narcissus* described, and yet I should be slow to say that in such flowers

no duplication of the corona has taken place, for in the variety just referred to it is very clear from the different colours that the corona is split up. It has been said of *N. Capax* that the multiplication of parts is "entirely confined to the perianth segments." Viewed in the light revealed by the particular variety of *N. Pseudo-Narcissus* referred to, and some forms of double *Telamonius*, there is in my opinion very little ground for this assertion, and it appears to be constructed upon a very superficial basis. Such stellate forms of double *Telamonius* I observe are not so vigorous, being much dwarfer when planted side by side with others, and there is also a greater uniformity of colour—indeed, more colour—than in the larger and more duplex forms; but in all the varieties you get the peerless-like perfume. I may here repeat my question as to whether this results from mere increase of coloured segments, or has it been infused by cross-breeding from *N. incomparabilis*?

N. grandiplenus is a very full flower, more often than not freely mixed and tipped with green, and the flowers are almost too heavy to stand erect. *N. lobularis plenus* is a very doubtful name; it evidently belongs to the *Telamonius* section, but has originated from a smaller flower, most likely from what is known as *lobularis*, which is in my

others, which are, however, not so distinct; the first form is especially variable both in number of segments developed and the colour. Several other duplex forms might be mentioned, but as there is little difference of opinion respecting them it is unnecessary to occupy any more space.—T.

IPOMÆA THOMSONIANA.

IPOMÆAS are great favourites amongst the best of roof-climbing plants for stoves, and several of them yield some of the richest tints of purple and crimson. There has, however, hitherto been a deficiency of light-coloured varieties, and that want has been most admirably supplied by the *Ipomæa Thomsoniana* (fig. 104), which Mr. B. S. Williams has introduced. It resembles *I. Horsfalliæ*, and was regarded as a variety of that until Dr. Masters determined it to be distinct, and honoured it with the above name. The flowers are larger than those of *I. Horsfalliæ*, and are borne in handsome wreaths clustering closely along the branches at

FIG. 104.—IPOMÆA THOMSONIANA.

opinion only a major development of *nanus*, hence you generally get this variety from the continent under the name of *N. nanus plenus*. I had a variety from Mr. Barr under the name of *N. lobularis plenus odoratissimus*, but could not distinguish any difference between it and the ordinary form.

There are at least three double forms of *N. incomparabilis*. 1, Which may be regarded as a duplex form of the typical *N. incomparabilis*; the perianth divisions are sulphur, while the duplicated coronal segments are deep yellow. This is known as "Eggs and Bacon." 2, Perianth divisions sulphur, while the coronal segments are deep orange—a very striking contrast, rendering the flower very attractive; known under the common name of "Butter and Eggs." This has, I think, originated from the variety *aurantius*. 3, Perianth division pale sulphur or creamy white, freely duplicated, while the pale coronal segments are but sparingly developed, the flower having a bold Rose-like appearance, and has probably originated from the variety *albus*. All three are very handsome and vigorous varieties, and should be extensively grown; the last is particularly desirable for pot culture. Beside these there are several

every axil, and have a fine effect when the plants are trained to the roof of a stove. The flowers are beautifully formed, the limb being quite circular, contracted below into a funnel-shaped tube. The leaves are rich green, thick, and have three neat oval leaflets. It is undoubtedly a most welcome addition to our list of indoor climbing plants, and will in a few years become an inhabitant of many gardens.

VINE GROWTHS.

SINCE writing before on this subject I have referred to Mr. Pearson's book on the Vine, published at the Journal office in 1880, and I ask to be allowed to add that in it I do not find any mention whatever of the practice recorded by "A Kitchen Gardener" as being associated in his mind with Mr. Pearson's practice. On the contrary, at page 19, Mr. Pearson recommends strong Vines to be cut back in the usual old way, and weak ones to be cut down nearly to the bottom of the rafter. At page 21 he

says, "that Vines properly treated ought to be in a good bearing state the third year; at any rate for 8 or 9 feet up the roof." "A Kitchen Gardener" said 12 feet the first year, and he therefore can be no disciple of Mr. Pearson. Mr. Pearson is, however, at one with myself in thinking that the more growth the stronger the cane, for he writes at pages 18 and 19—"Let the leader make all the wood it can... the more healthy fully exposed foliage the Vine makes the more roots it will have, and the stronger it will grow."—NON-BELIEVER.

ROSE HER MAJESTY.

Your correspondent "J. A. W." in his article on "Big Roses" in the *Journal of Horticulture* of May 15th, page 378, commenting on the Rose Her Majesty, states, "I can only believe the raiser looks on this as a monstrous curiosity," and that it will not be sent out in this country. To both of these statements I give the fullest and flattest contradiction. "J. A. W." is quite unknown to me, therefore cannot have been in my confidence, and I consider his assertion unwarrantable.—H. BENNETT, Shepperton.

MANCHESTER WHITSUNTIDE SHOW.

MAY 30TH TO JUNE 6TH.

SEVENTEEN annual exhibitions have now been held at Whitsuntide in the gardens of the Royal Botanical and Horticultural Society at Manchester, and after such a long career it is pleasant to be able to record that their last Show was in many respects the finest they have ever held. It was undoubtedly the largest, the competitors being more numerous, and the general beauty of the Exhibition has never been surpassed. There were of course a few weak classes, but the grandeur of the Orchids compensated for every defect of this kind, and the fine-foliage plants with Ferns were in admirable health.

The most important portion of the display was that contained in the magnificent new exhibition house, which is the finest structure of its kind in the country. It is over 200 feet long and 50 feet wide, well proportioned, and elegant in design, having a central table and two side beds. The former was occupied with miscellaneous groups—Pitcher Plants, table plants, bouquets, &c., the side beds being devoted to the stove and greenhouse plants, fine-foliage plants, and Orchids. The last named formed handsome banks of richly and delicately tinted flowers; but the grandest feature was at the end of this building, where Mr. Percival's wonderful specimen Orchids were placed, with a background of Mr. Schloss's superb *Gleichenias*—a contrast of extreme beauty such as we have never seen equalled at a public show. In the other portion of the house the *Crotons*, *Dracenas*, and *Palms* formed the background to the numerous collections of Orchids, the stove and greenhouse plants being arranged near the entrance.

The spacious marquee which contained the groups of plants arranged for effect, the *Rhododendrons*, *Clematises*, *Roses*, and some smaller classes. On the slope of the mound at the end near the entrance there was a ridge of Messrs. R. Smith & Co.'s charming *Clematis*, neat globular specimens beautifully flowered; below these were Mr. C. Turner's Show and Fancy *Pelargoniums*, fresh, healthy, profusely flowered specimens. Beyond these again was a central circular stage bearing Mr. Turner's brilliant *Azaleas*, and surrounded by small *Roses*, *Calceolarias*, and *Cinerarias*. Very prominent on the left looking towards the end of the marquee was a magnificent group of choice stove and greenhouse plants in flower from Messrs. Cutbush and Son, which attracted very much admiration; then there were the groups in competition, Messrs. R. P. Ker's tasteful contribution and Messrs. Birkenhead's exquisite bank of Ferns being the most important features; while at the end were grand banks of *Rhododendrons* from Messrs. John Waterer and Sons, Bagshot, which furnished abundant shades of crimson, purple, rose, and scarlet. In this marquee, as in the exhibition house, the most careful attention had been given to the arrangement of the exhibits, the brightly coloured flowers being softened and contrasted with foliage plants in due proportion, producing a general effect of extreme beauty.

In a long tent parallel with the exhibition house were the majority of alpine and herbaceous plants, which are never shown at any exhibition in England in such numbers and quality as at Manchester. *Pelargoniums*, *Calceolarias*, and a few miscellaneous collections, together with the fruit, and on Saturday, with the beautiful display of Tulips from the National Tulip Society, completed the attractions of this tent, which added materially to the extent and interest of the Show.

The Committee and the Curator, Mr. Bruce Findlay, deserve much praise for the energy they display in connection with this Society, which they have raised to a foremost position, and which in the north of England assists so greatly in fostering a love for horticulture, not only amongst the wealthy, but amongst the poorer classes. The appreciation in which it is held is abundantly proved by the numbers of visitors that assemble in the gardens during the holidays, and fortunately, though the weather was exceedingly gloomy on the first two days, it became brighter on Sunday and following days, with the result that the Exhibition was, as usual, thronged.

ORCHIDS.

At no exhibition throughout England is such liberal provision made for Orchids as at Manchester, and as a natural result the display is larger, more varied, and more beautiful than can be seen elsewhere in the kingdom. Independent of the numerous other exhibits which render the Whitsuntide Show of such magnitude and interest, the Orchids alone constitute an exhibition of unequalled attractions, and one which would be worth a long journey to see. In the neighbourhood of Manchester there are a number of enthusiastic and wealthy amateurs, who usually spend large sums of money on purchasing the newest or choicest species or varieties, and in growing fine specimens, and the prizes are good enough to induce not only these to contribute their valuable plants, but also growers from a great distance. There is besides a great local interest and pride in their famed national show, and every effort is made to render it worthy of its name; indeed, it is difficult to imagine a more beautiful display than that provided in the handsome new exhibition house, which, being properly heated, prevents that

injury to the plants which is too often the result of staging such plants in the ordinary tents. A wealth of colours, from the brightest gold and scarlet to the richest crimson, like this could only be afforded by Orchids, and every visitor on entering the house was amazed by the effect.

Eight classes were devoted to Orchids, six being for amateurs, with a total in prize money of £104; and two to nurserymen, with a total of £52, the first prizes ranging from £16 to £3. In the majority of these the competition was keen, and the plants staged quite up to the usual standard—healthy and well flowered. The principal amateurs' class was that for fifteen Orchids in flower, the prizes being £16, £12, and £7. In this there were three exhibitors, Mr. G. Beddoes, gardener to R. P. Percival, Esq., Cleavelands, Southport, taking premier honours for grand specimens 3 or 4 feet in diameter, comprising *Lælia purpurata*, with about eighty large flowers; *Cattleya Mendelli*, with fifty flowers—fresh, bright, and even; a large pan of *Odontoglossum Alexandræ*, with about thirty spikes; *Dendrobium thysiflorum*, with twenty-six grand spikes, very handsome; *Odontoglossum vexillarium*, bearing over forty magnificent racemes of richly coloured flowers; *Thunia Bensoniæ*, with two dozen growths, each with four or five rosy purple flowers; *T. Marshalliæ*, very strong and healthy, but not quite forward enough; *Cypripedium barbatum*, with three dozen flowers; *Anguloa Clowesi*, with twenty flowers; *Dendrobium nobile*, 4 feet in diameter, with hundreds of flowers; *Dendrobium fimbriatum oculatum*, similar; *Oncidium concolor*, in a basket 3 feet square; *Vanda suavis*, with two spikes; and *Dendrobium Jamesianum*, with about twenty flowering growths. This was a magnificent collection, and well merited the award it received.

Mr. J. Holmes, gardener to D. Schneider, Esq., Cromwell Range, Fallowfield, was placed second, his best specimens being *Dendrobium Wardianum*, with over 100 flowers of a fine variety; *D. Dalhousianum*, with two dozen grand spikes of six to seven flowers each; and *Aerides odoratum purpurascens*, with seven spikes. Mr. Swan, gardener to W. Leech, Esq., Oakley, Fallowfield, was third with smaller but healthy well-grown plants.

For nine Orchids there were three exhibitors, Mr. Beddoes again taking the lead with a magnificent *Dendrobium chrysotoxum*, with over thirty spikes of ten or a dozen flowers each. *Cattleya Mossiæ*, *Odontoglossum vexillarium*, *D. thysiflorum*, and *Cattleya Mendelli*, all in fine condition, *D. formosum giganteum* being also very handsome with twenty-six large flowers. Mr. Holmes secured the second place with a neat fresh collection, comprising a very handsome *C. Mossiæ*; and Mr. Mitchell, gardener to Dr. Ainsworth, Cliffe Point, High Broughton, took the third position with small fresh plants. The competition was keen in the class for six Orchids, the best collection being those from Mr. Mitchell, in which the heaviest specimen was *Phalaenopsis amabilis*, bearing forty spikes of four or five flowers each, large and clean. *Saccolabium præmorsum* with two spikes and *Cattleya Mossiæ* with two dozen flowers were also noteworthy specimens. Mr. Swan was a close second, having *Odontoglossum Alexandræ* and *cirrhum* very handsome, *Vanda suavis* with three grand spikes, and *Aerides Fieldingi* with five large spikes. Mr. G. Waddell, Orchid grower to Joseph Broome, Esq., Wood Lawn, Didsbury, being third with a beautiful *Vanda teres* bearing thirty flowers, having others that were in full health though small.

The interesting class for ten *bonâ fide* specimens brought four collections, Mr. Beddoes winning first honours with *Lælia purpurata* bearing thirteen spikes of three and four flowers each, a healthy vigorous specimen; *Odontoglossum citrosum* with two spikes; *Cypripedium Dominionum* with seven flowers; *Cattleya Sanderiana* with two spikes of four and five flowers each, grandly coloured; *Cattleya Mossiæ* with thirty flowers and buds; *Vanda suavis* with two spikes, ten flowers; and *Odontoglossum vexillarium*, beautifully coloured, with sixteen fine spikes of six and seven flowers each; *Anguloa Ruckeri* with eight flowers, and *Cypripedium caudatum* with eight flowers. Mr. Waddell was placed second; his best plant, and one of the finest of its kind in cultivation, was *Vanda teres* 5 feet high and as much in diameter, bearing about fifty spikes of three or four flowers each. Several good *Dendrobiums* were included, *D. Freemani* being remarkably well flowered. Mr. Holmes was third with *Dendrobium nobile intermedium*, 4 feet high and through, having hundreds of light-coloured but pretty flowers.

The nurserymen's classes were not remarkable for any very large specimens, Mr. Cypher, Cheltenham, being first with sixteen specimens, mostly of moderate size; *Dendrobium thysiflorum* having fourteen spikes, *Cypripedium Lawrenceanum* eleven fine blooms, and *Dendrobium Falconerii* on a raft, with very handsome richly coloured flowers, one of the finest varieties we have seen. Mr. H. James, Lower Norwood, was a close second, his collection being slightly less effective than the other, but containing fine plants of *Oncidium Marshallianum* and *Cypripedium barbatum*. Messrs. Heath & Son, Cheltenham, followed with well-flowered plants. In the class for ten specimens, however, Mr. H. James was a good first with a beautiful group, comprising *Odontoglossum vexillarium*, very deeply coloured; *Odontoglossum Alexandræ*, with six spikes of large beautiful flowers; *Cypripedium barbatum grandiflorum*, with twenty-two flowers; *Epidendrum vitellinum majus*, with eighteen spikes; and *Odontoglossum cordatum aureum*, with six spikes. Mr. Cypher was second with showy well-grown plants of *Dendrobium Dearii*, with three spikes of seven to nine flowers each; *Dendrobium thysiflorum*, with sixteen spikes not quite out; *D. Bensoniæ*, and *D. Wardianum* finely flowered. Messrs. Heath & Son were third with small plants. Only two collections of three *Vandas* were staged; Mr. M. Bailie, gardener to the Earl of Wilton, Prestwich, winning the premier honours with three handsome plants 4 feet high, two plants of *V. suavis*, and one of *V. tricolor* with two spikes each. Mr. G. Jackson, gardener to S. S. Whalley, Esq., secured the second place with three plants of *V. suavis* 2 to 4 feet high, one having one spike and two a pair of spikes each.

Altogether it is doubtful if so large a public exhibition of Orchids has ever been seen, and most conclusive evidence was afforded of how high a position these plants hold in popular estimation, and the great care bestowed upon their culture. It is true that some might object to several rather markedly packed specimens of the "made-up" type, but they serve to make a good show, and this, by attracting the people, insures the success of the Exhibition. However, to gratify those who prefer the *bonâ fide* single specimens a class was specially provided, and that is really all that can be done by managers of horticultural shows, as to exclude all others would be ruinous.

FINE-FOLIAGE PLANTS.

Next in importance to the Orchids were the fine-foliage plants, and these were all uncommonly well shown both as regards numbers and general good quality. The principal class for amateurs was for ten specimens; and in this Mr. G. Smith, gardener to J. Rylands, Esq., Stretford, won the leading honours with an extremely well-grown collection, comprising magnificent plants of *Croton Weismanni*, *Pritchardia pacifica*, *Cibotium Schiedei*, *Cycas revoluta*, *Areca lutescens*, and *Alocasia Lowii* of great size, and in the case of the *Croton* and *Alocasia* finely coloured. A close second position was gained by Mr. Paul, gardener to S. Schloss, Esq., Bowdon, who had particularly good examples of *Anthurium Veitchii*, *Cycas revoluta*, *Zamia Lindenii*, and *Gleichenia Mendellii*. Mr. Roberts, gardener to E. Cliffe Glover, Esq., Leek, was third, showing *Latania borbonica*, *Ptychosperma Alexandræ*, and *Kentia Belmoreana*, handsome in size and health. In the nurserymen's class for eight specimens Mr. Cypher, Cheltenham, gained the premier prize with praiseworthy examples of *Cordyline indivisa*, *Cycas circinalis*, *Latania borbonica*, *Cycas revoluta*, *Croton Williamsii*, and *Kentia Canterburyana*, the remaining prizes being secured by Mr. H. James of Lower Norwood, London, and Mr. E. Tudgey, Waltham Cross, whose plants have already this season made a good appearance at several leading shows in the south of England.

Crotons.—These were magnificent, of special importance being the beautiful collection of ten from Messrs. R. P. Ker & Sons, Liverpool, which secured them first honours in the nurserymen's class. The Liverpool plants are remarkable alike for their clean vigorous growth, their rich colours, and for the fact that they are mostly confined to one stem, a mode of culture which appears to suit them admirably. The varieties represented were princeps, Queen Victoria, interruptus aureus of wonderful colour, Baroness Rothschild, Hawkeri, Evansianus, Weismanni, Warreni, and Williamsi. Mr. H. Cole, gardener to J. Broome, Esq., Wood Lawn, Didsbury, was the most successful amongst the amateurs in the class for six *Crotons*, showing fresh highly coloured plants of *Andreanus*, Prince of Wales, Williamsi, Evansianus, and Queen Victoria, 3 to 4 feet high, bushy and handsome specimens. Mr. Roberts took the second place with similarly well-grown plants, his best specimens being *Hawkeri* in grand condition, *Johannis* very elegant, and *Baron F. de Rothschild*. Mr. C. Paul was third with rather poorly coloured plants.

Dracænas.—In the nurserymen's class for twelve specimens Messrs. R. P. Ker & Sons were the premier exhibitors, showing a beautiful collection, which, like the *Crotons*, were finely coloured. The varieties were *Macleayi*, *Rebecæ*, *Alba marginata*, *Gladstonei*, *Mooreana*, *Goldieana*, *Salmonea recurva*, *Lindenii*, *Mrs. G. Freake*, and *Baptisti*. They were from 2 to 5 feet high, well proportioned, and clothed with foliage down to the pots. Mr. H. James was a good second, having especially fine examples of *Shepherdii* and *Mooreana*. Mr. Cole won the first position in the amateurs' class for six *Dracænas*, staging fresh healthy plants 3 to 5 feet high of *Goldieana*, *anerleyensis*, *Baptisti*, *Shepherdii*, *Youngii*, and *Weismanni*; Mr. Williams, gardener to S. Baerlein, Esq., Didsbury, being second with fine plants of *Lindenii*, *indivisa*, and *Rossi* amongst others; and Mr. Kemp, gardener to Mrs. Sykes, Etgley House, Stockport, was third with a similar collection of smaller plants. There were six competitors in this class, and the exhibits were very close in merit. Palms were well shown by Messrs. Tudgey, Cypher, and James in the nurserymen's class, and by Mr. G. Williams in the amateurs' class, all having large well-grown specimens.

Yuccas were well staged by Mr. G. Smith, who had the best four plants, 5 feet high and well coloured, the varieties being *quadricolor* and *aloifolia variegata*. Mr. Cole was second with dwarf but very healthy examples of *Stokesii* and *aloifolia variegata*.

Ferns.—Very rarely is such a magnificent collection of *Gleichenias* seen at shows as that with which Mr. C. Paul gained the premier prize in the class for eight stove and greenhouse Ferns. These were 6 or 7 feet in diameter and in perfect health, covered with vigorous fresh green fronds, which had a beautiful appearance behind the Orchids. The species represented were *G. Speluncæ*, *G. glaucescens*, *G. flabellata*, and *G. Mendellii*. With them were shown good specimens of *Dicksonia antarctica* and *Goniophlebium subauriculatum*. Mr. Baillie, gardener to the Earl of Wilton, followed closely, having smaller but well-grown plants of *Adiantum Flemingii*, *Acrophorus immersus*, and *Davallia bullata*. Mr. Roberts was third, his best plants being *Dicksonias* and *Cyatheas*.

For twelve hardy Ferns Mr. R. Tyldesley, Worsley, secured chief honours for a wonderfully handsome collection of large vigorous specimens. Especially notable were *Athyrium Filix-femina Vernoniæ*, *Osmunda regalis purpurascens*, *Athyrium F.-f. Craigii*, *Polystichum angulare plumosum* very beautiful, *Lastrea furcans*, and *Polystichum angulare Wollastoni*. This exhibitor is a collier, and, like many working men in the north of England, he makes a special study of Ferns, devoting all his spare time to their cultivation. Mr. Broadman took the second prize, his best plants being *Athyrium Filix-femina fissidentatum* and *Onoclea sensibilis*. Mr. J. Hesketh, gardener to H. Birley, Esq., Pendlebury, followed with several handsome *Polystichums*, *Osmundas*, and *Lastreas*. Mr. G. Smith had the best collection of six Filmy Ferns, very pretty specimens of *Todea superba*, *Hymenophyllum demissum*, *Todea pellucida*, *T. radicans*, and *T. superba*.

Pitcher Plants.—A surprisingly fine display of these was formed, and seldom is so large a number of such plants seen at exhibitions. They constituted a feature of great interest in the Exhibition house, and attracted almost as much attention from the visitors as the Orchids did. Mr. Cole had the best ten specimens in the amateurs' classes—wonderfully fine plants, some of them, as *Nepenthes Rafflesiana*, bearing dozens of grand pitchers, while *M. Mastersiana* with ten large deeply coloured pitchers has probably never been surpassed; *N. Kennedyana* and *N. Williamsii* were also good. The *Sarracenias* were in similarly creditable condition, one example of *S. purpurea* being over 3 feet in diameter and grandly coloured. Mr. Holmes followed, chiefly with *Sarracenias*, splendidly coloured plants of *S. Mitchelliana*, *S. purpurea*, *S. Chelsoni*, and *Nepenthes Hookeri* being the chief features of his collection. Mr. J. Morton, gardener to J. Fildes, Esq., Chorlton-cum-Hardy, was third with healthy but not so brightly coloured specimens. Only one collection was entered in the nurserymen's classes for ten plants, Mr. H. James being awarded the premier prize for the large specimens which were so much admired at the Crystal Palace Show recently.

Sonerilas.—It is seldom that a class is provided for these beautiful little plants, but at Manchester they receive the attention they so well merit. Two

collections of six plants were staged, Mr. Cole being first with charming specimens in pans, the foliage being beautifully marked; especially pretty were *margaritacea*, *Hendersoni*, and *argentea*. Mr. G. Williams followed with similar plants and varieties, except *amœna*, an extremely pleasing form with silvery dots on a deep green ground.

HERBACEOUS AND ALPINE PLANTS.

In the amateurs' class for thirty herbaceous and bulbous plants in or out of flower the first prize was taken by Mr. H. G. Bennett, gardener to T. Dickens, Esq., Higher Broughton, followed very closely by Mr. T. Entwistle, gardener to Joseph Broome, Esq., of Didsbury. In the first collection the most conspicuous plants were *Thalictrum aquilegifolium*, *Saxifraga pyramidalis*, *Hemerocallis flava*, *Trollius asiaticus*, and *Pæonia tenuifolia* fl.-pl. The second collection was on the whole, we consider, equal to if not superior to the first, but adjudication was difficult on account of the groups being arranged in different tents. The following plants were especially well shown:—*Lilium longiflorum*, *Lilium philadelphicum*, *L. Brownii*, *L. tigrinum* fl.-pl.; *Geum aurantiacum*, *Achillea tomentosa*, *Pyrethrum Penelope*, *P. amethyst*, *Delphinium Belladonna*, *Thalictrum purpurascens*, *Dodecatheon integrifolium*, &c., all of which give evidence of the best culture. In the class for thirty alpine plants Mr. Entwistle was well to the front with a most interesting and prettily arranged collection, neatly labelled, and in every way most commendable, including good pans of *Veronica prostrata*, *Saxifraga Mawiana*, *Saxifraga pyramidalis*, *S. Valdensis* (very fine), *Campanula Portenschlagiana*, *Saxifraga carinthiaca*, &c. In the class for twelve alpine plants the same exhibitor was a long way ahead with a charming group, including a magnificent pan of *Sempervivum arachnoidum* about 18 inches across, prettily covered with its white web; *Phyteuma comosum* well in flower, *Campanula thyrsoidea* with a magnificent spike over a foot long of its bell-shaped sulphur-coloured flowers; this and the last plant are very rare, and were never seen in better condition; *Dianthus glacialis*, *Allium pedemontanum* well in flower, and *Delphinium nudicaule*. The second prize was secured by Mr. James Mellor of Didsbury.

In the classes provided for nurserymen the premier position for sixty herbaceous and bulbous plants in or out of flower was awarded to Mr. A. Walkden of Sale with a very neat collection, mostly varieties of florists' flowers, including numerous *Pyrethrums*, double *Rockets*, *Pinks*, *Aquilegia cærulea*, *Cheiranthus Marshalli*, *Primula farinosa* (the best pan in the collection), *Delphinium nudicaule*, *Anthericum liliastrium*, *Geum coccineum* fl.-pl., *Thalictrum aquilegifolium*, &c. Messrs. James Dickson & Sons, Newton Nurseries, Chester, were a very close second, and their collection included some very fine plants, including a very large specimen of *Lilium longiflorum*, some of the stems carrying five fine flowers; the variegated form of this Lily was also good, and for such a rare form very striking; *Cypripedium pubescens*, *Narcissus bulbocodium*, *Gladiolus The Bride*, *Orchis foliosa*, very fine, with nine large spikes of bloom; *Aquilegia rubra-alba plena*, very showy; *Phlox ovata*, *Lilium auratum*, *Dianthus hybridus floribundus*, *D. hybridus Napoleon III.*, *Iberis gibraltarica hybrida*, *Ranunculus aconitifolius* fl.-pl., *Baptistia lutea*, &c., the whole forming a very attractive group. In the nurserymen's class for forty alpine plants Messrs. James Dickson & Sons of Chester were well to the front with a rich collection, including *Saxifraga cochlearis major*, *Ramonda pyrenaica* (a good pan), *Androsace lanuginosa*, *Phyteuma Scheuchzeri*, *Tropæolum polyphyllum*, *Erinus alpinus*, *Campanula Portenschlagiana*, *Sibthorpia europæa* and its variegated form; *Edelweiss*, a very fine pan; *Onosma taurica*, a most beautiful specimen, &c., the whole forming a most interesting and very much-admired group. Messrs. F. W. and H. Stansfield, nurserymen, Sale, were second, whose collection included a beautiful pan of *Saxifraga McNabiana*, one of the finest of the encrusted section.

Pansies and Violas.—Amateurs' classes.—Six Show in 8-inch pots: First Mr. T. Entwistle with *Jupiter*, *Queen*, *Clonard*, *Marquis*, *Royalty*, *Tickle*—a well-shown fine lot. Second Mr. James Mellor, Didsbury; third Mrs. C. Sergeant Sale. Six Fancy varieties in the same sized pots: First Mr. J. Blower, Pendlebury, with *Champion*, *Mrs. E. H. Wood*, *Richard Tonge*, *Gold-digger*, *Mrs. Scott*, *Plummer*, and *Mrs. Jamieson*. A very close second was gained by Mr. Entwistle with *Thomas Grainger*, *John Strattan*, *John Currie*, *Mrs. Felton*, *Christine*, *Miss Freeman*. Third Mrs. C. Sergeant, Sale. The Fancy varieties were excellent, and there was close competition, all the collections being good. Six *Violas* in 8-inch pots.—These were especially well shown. First Mr. Rose, gardener to D. McClure, Esq., Heaton Mersey, with *Pilgrimage*, *Holyrood*, *Picturata*, *Admiration*, *Alpha*, and *Sovereign*. Second Mr. T. Entwistle with fine pots. Third Mr. H. G. Bennett, gardener to Thos. Dickens, Esq., Higher Broughton. Nurserymen's classes.—Twenty Show varieties in 8-inch pots: There was very close competition in this class, the premier position falling to Mr. John Hayward of Cheadle near Manchester. Amongst the best varieties were *Yellow Queen*, *Black Sam*, *Duke of Perth*, *Dr. Hardy*, *A. Grant*, *Col. Wedderburn*, *Leith Walk Hero*, &c. Second Mr. W. Saunders, Leek. Twenty Fancy varieties in 8-inch pots: Mr. Hayward again taking the lead with a very even lot, although the flowers were not so large as could be desired. Amongst the best were *W. P. Fairgrieve*, *George Wood*, *Emblem*, *T. Grainger*, *Lady Hay*, *Countess of Strathmore*, *Miss Darling*, *Major Molesworth*, *Wm. Melville*, and *Mrs. Birkmyre*. Second Mr. F. Walkden, Sale; third Mrs. Eliza Mellor, Chorlton. Twenty *Violas* in 8-inch pots.—In this class Mr. Hayward most conspicuously took the lead with charming pots, very evenly put up, including *Pilgrimage*, *Sovereign*, *Admiration*, *Countess of Kintore*, *Beauty of Sale*, *Archibald Grant*, *Max Kolb*, and *King of the Blues*.

GROUPS.

Two classes were devoted to these, one for groups 30 by 15 feet, and the other 25 by 12 feet. In the first named there were two entries, both remarkably beautiful and novel, and though differing greatly in character they were nearly equal in merit as regards the taste manifested in their arrangement. Messrs. R. P. Ker & Son were awarded first honours for a group which could scarcely be surpassed in effectiveness and grace. There was a bold central mound of *Palms*, *Azaleas*, *Crotons*, *Ferns*, and *Cordylines*, the general groundwork being an undulating surface of *Adiantums*, with small *Crotons*, *Dracænas*, *Caladiums*, and *Pelargoniums*, with taller examples of the slender-leaved and drooping *Crotons* rising from amongst them. There was a neat margin of pink *Pelargoniums* alternating with variegated *Grasses*,

the general arrangement of the group being all that could be desired. Many admiring comments were passed upon this group by the visitors, and Messrs. Ker deserve the greatest praise for the care they gave to the work. Second honours were gained by Messrs. W. & J. Birkenhead, Sale, for an exquisitely graceful arrangement of Ferns, comprising a large number of choice varieties disposed in the most elegant manner imaginable. It has already been proved at the Brighton Shows what beautiful effects can be produced by tastefully arranged groups of Ferns; and Messrs. Birkenhead's group was welcome evidence that similar attempts to popularise this style of decoration are being made in the north. It is true that it is impossible to obtain from Ferns that brilliance which is sometimes desirable in a show, but as a rule there is abundance of flowers, and the soft varied shades of green form a most agreeable contrast and relief to the floral portion of an exhibition. In the group in question there was a central branching tree-like stem of cork, which was covered with Selaginellas and Ferns, the general foundation of the group being formed of Adiantums of approved species and varieties, with taller plants suitably introduced to vary the surface. The whole group was well finished, with the exception perhaps of the margin, which would have been improved had the pots been concealed.

The amateurs' classes contained three exhibits, but with the exception of the first-prize group from Mr. G. Smith they were rather deficient in tastefulness of arrangement. The leading group contained a due proportion of flowering and fine-foliage plants on a ground of small Ferns, Panicums, Crotons, and Caladiums, with a neat margin of Gloxinias. Mr. Roberts was second with a bright group, flowering plants predominating; and Mr. Paul was third with a rather rough group, including several very poor Azaleas.

NEW PLANTS.

Foremost with twelve new and rare plants were Messrs. R. P. Ker & Son, who staged good plants of the following, which have been previously described in these pages:—*Davallia fijiensis*, *Azalea roseiflora*, *Anthurium ferrierense*, *Schismatoglottis Robelini*, *Ficus elastica alba variegata*, *Aralia amboinensis*, *Licuala grandis*, *Areca Verschaffelti pendula*, *Cyathea Dregei*, *Carludovicia atropurpurea*, *Croton Flambeau*, and *Pritchardia Vuylstekiana*. Mr. H. James took the second place with *Dieffenbachia Jenmani*, *Acer polymorphum sanguineum*, *Anthurium Schertzerianum* Hendersoni, *Panax Victorice*, *Nepenthes Mastersiana nigra*, a very dark-pitched form; *Masdevallia Chelsoni*, *Selaginella involvens variegata*, *Anthurium ferrierense*, *Odontoglossum polyxanthum*, *Cypripedium superciliale*, *Lælia purpurata virginialis*, and *Oncidium nigratum*. Mr. Cole had the best six new and rare plants, which comprised the following:—*Sarracenia Swanniana*, *S. Atkinsoniana*, *Nepenthes bicalcarata*, with twelve grand pitchers and fully 6 feet in height, a magnificent specimen; *Dracæna Lindenii*, and *Nepenthes robusta*.

STOVE AND GREENHOUSE PLANTS.

The principal class was that for ten specimens, in which three collections were staged, including some beautiful plants. Mr. Cypher was adjudged premier honours for a fresh and handsome collection, comprising *Erica Cavendishiana*, grandly flowered and in most vigorous health, *Dracophyllum gracile* was similarly praiseworthy; *Hedera tulipifera*, *Franciscea eximia*, *Erica depressa*, 5 feet in diameter and superbly flowered, *Aphelaxis macrantha purpurea*, and *Bougainvillea glabra* were other noteworthy specimens in what was by far the best collection of these plants in the Show. Mr. H. James secured the second place with good examples of *E. Cavendishiana*, *Statice profusa*, *Genetyllis Hookeri*, *Anthurium Andreanum*, and *Erica depressa*. Mr. E. Tudgey was third with several well-grown Heaths. The first position with eight specimens was gained by Mr. C. Paul, who had *Stephanotis floribunda* of globular form, *Erica Cavendishiana* profusely flowered, and *Acrophylum venosum* very beautiful. Mr. G. Smith followed closely, his two best plants being *Erica perspicua nana* 5 feet in diameter, and *Allamanda grandiflora* about the same size. Mr. Roberts was third with smaller specimens.

Ericas.—Four collections of six *Ericas* were staged, two in the amateurs' and the same number in the nurserymen's class. In the former Mr. Cole took the lead with even healthy specimens, followed by Mr. G. Williams; while in the other class Mr. Cypher was the most successful, having half a dozen charming plants, 3 to 4 feet high, globular in form and profusely flowered. *E. Cavendishiana*, *E. ventricosa coccinea minor*, *E. affinis*, *E. ventricosa magnifica*, and *E. ventricosa rosea* were the varieties. Mr. Tudgey was a close second with neat plants well flowered.

Azaleas were not so good as might have been desired, with the exception of Mr. C. Turner's plants, which won him premier honours. These, as already noted, formed a beautiful central group, and were, as the Slough plants always are, in grand condition. The best *Pelargoniums*, both Show and Fancy varieties, were also from Mr. Turner, superbly flowered specimens, which Mr. C. Ryland of Ormskirk could not equal, though he showed some good specimens. The amateurs' productions in these classes were not of first-rate merit, *Cinerarias* being also rather poor.

Clematises were grandly represented by Messrs. Richard Smith of Worcester, who secured the first-prize for fifteen plants, globular specimens, well flowered and evenly trained. Messrs. G. Paul & Son, Cheshunt, had the premier position with twenty *Roses* in pots. The plants were 3 to 4 feet high, compact, healthy, and beautifully flowered, the colours of the blooms being especially rich and clear. Messrs. G. & W. Yates, Manchester, were second in the same class with dwarf specimens, and Mr. Tudgey was third with small plants.

Gloxinias and *Calceolarias* made a good display, the former being particularly well flowered. For ten *Gloxinias* Mr. F. Long, Prestwich, secured the first position with healthy plants bearing two or three dozen flowers. Mr. J. Franklin, gardener to P. Am. Ende, Esq., Whalley Range, and Mr. T. Eden, gardener to Mrs. Sargent Sale, following amongst seven exhibitors. Eight collections of ten *Calceolarias* were staged, Mr. G. Coulson, gardener to A. Schill, Esq., Didsbury, leading with compact healthy plants of a good strain. Mr. J. Hay, gardener to Mrs. Tootal, The Waste, Pendleton, followed; and Mr. C. Collings, gardener to J. M. Heatherton, Esq., Victoria Park, was third. In the nurserymen's class for twelve plants Messrs. R. P. Ker & Son and Mr. J. Taylor, Huyton, Liverpool, were the prizetakers.

Table Plants.—The competition was exceedingly keen in the class for six table plants, no less than eleven collections being staged, all neat and suitable plants. Mr. J. Hill, Rochdale, was first with graceful little specimens

of *Aralia leptophylla*, *A. elegantissima*, *Kentia Belmoreana*, *Pandanus Veitchii*, *Cyperus alternifolius variegatus*, and *Dracæna Bausei*, the surface of the soil being covered with *Sibthorpia europæa* and *Selaginellas*. Mr. G. Park, gardener to R. H. Harrington, Esq., Wigan, and Mr. T. Moss, Preston, were the other prizetakers, each showing neat elegant plants.

Bouquets.—Several very tasteful bouquets were entered. In the amateurs' class for two Mr. Plant, gardener to R. P. Gill, Esq., Woodheys Hall, Ashton-on-Mersey, was first with a choice arrangement of Orchids, *Roses*, *Gloxinias*, *Stephanotis*, *Ixoras*, *Dipladenias*, and Ferns. Mr. Collins was second, chiefly with *Eucharis* and Orchids, while Mr. Elphinstone, gardener to J. Heywood, Esq., The Grange, Stretford, was third with a combination of *Maréchal Niel* *Rose* buds and *Epidendrum vitellinum* flowers. For three bouquets Mr. Cypher was first, having handsome bouquets of Orchids, *Pancratiums*, and white *Lapagerias*; Mr. Chard, Clapham Common, Mr. T. Walkden, Sale, and Messrs. Sherratt & Pointon, Congleton, following.

FRUIT.

Though the display of fruit was not large it was good for the time of year, the black Grapes being especially well shown, good in bunch and berry, and generally well coloured. Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, was the premier exhibitor of eight dishes of fruit, showing Foster's Seedling and Black Hamburgh Grapes, the former of good size and the latter well coloured. A neat Queen Pine weighing 3½ lbs., good Elrue Nectarines, fine Stirling Castle Peaches, ripe Brown Turkey Figs, and a richly coloured Golden Gem Melon. Mr. McIndoe, gardener to Sir Joseph Pease, Bart., M.P., Hutton Hall, Guisborough, was second with Early Saumur, Frontignan, and Madresfield Court Grapes, the latter well coloured, Best of All Melon finely netted, Bellegarde Peaches large, and Lord Napier Nectarines scarcely ripe. Mr. Upjohn, gardener to the Right Hon. Lord Ellesmere, Worsley Hall, was third, having Black Hamburgh Grapes rather wanting in colour, and Peaches and Nectarines scarcely so ripe as might have been desired.

Fourteen exhibitors competed with two bunches of black Grapes; Mr. Church, gardener to C. S. A. Mellussen, Esq., Brodsworth Hall, Whitefield, leading with Black Hamburgh, fine in bunch and berry and handsomely coloured. Mr. J. Londen, gardener to Thos. Barnes, Esq., The Quinta, Chirk, was second with the same variety smaller in berry; and Mr. C. Breese, gardener to Mr. Ackers, Moreton Hall, followed with small bunches. Nine pairs of white Grapes were entered, Mr. Londen securing the first position with Muscat of Alexandria not fully ripe. Mr. R. J. Anson, gardener to W. Bretherton, Esq., Euxton, Chorley, was second with Foster's Seedling; and Mr. Miles third with the same. Canon Hall Muscat and Duke of Buccleuch were also shown, but were not in good condition. For one Pine Apple Mr. G. T. Miles was first with a Queen weighing 4 lbs., beautifully even and well ripened. Mr. Clayton, Grimston Park, was second with Smooth Cayenne neat and even. Mr. Miles was also first with two Pines, Queens, 4½ and 5 lbs. respectively. Mr. McIndoe was second with a smaller Queen, and Mr. Breese third with the same variety. Strawberries in pots were not very fine, Mr. G. Smith, Mr. Chuck, and Mr. Upjohn securing the prizes, the varieties best represented being Vicomtesse Hericart de Thury and La Grosse Sucrée.

There was a fair show of Asparagus, Mr. G. T. Miles securing the first prizes for eighty and fifty heads, Mr. Campbell, gardener to T. Higson, Esq., Oakmore Hall, Mr. T. Pitt, gardener, Berry Hill, and Mr. Mossman, gardener to G. Pollock, Esq., Windlesham, following.

Miscellaneous.—A large number of groups and collections were contributed not for competition, and added considerably to the interest of the Exhibition. Mr. B. S. Williams, Upper Holloway, was the principal exhibitor, and had a magnificent group in the exhibition house, comprising a large number of choice Orchids, new and rare flowering and fine-foliage plants very tastefully arranged. Messrs. F. and A. Dickson & Son, Chester, had a choice collection of stove and greenhouse plants, including a good plant of *Asparagus virgatus*, with a good proportion of the bright and pretty *Boronia elatior*; Messrs. Cutbush & Son, Highgate, London, had a large and handsome collection of greenhouse plants, including a great number of well-grown hard-wooded plants; Messrs. J. Laing & Co., Forest Hill, London, sent some new tuberous Begonias and Caladiums; Mr. C. Turner, Slough, showed a fine group of *Roses* in pots; Messrs. J. Waterer & Co., Bagshot, had extensive banks of *Rhododendrons*; The Liverpool Horticultural Company (John Cowan) limited, had a miscellaneous collection of Palms, *Pelargoniums*, and *Hydrangeas*; Messrs. R. B. Laird & Son, Edinburgh, sent several boxes of *Violas*, representing many choice varieties; and Mr. T. Bethell, Liverpool, sent samples of their unique folding boxes. Mr. Miles had a fine dish of Stamfordian Tomatoes; Mr. Milne, Vale Royal, dishes of Nectarines and Strawberries. For most of the above extra prizes were awarded.

THE FLOWER TENT AT THE BATH AND WEST OF ENGLAND SHOW AT MAIDSTONE.

JUNE 2ND TO 6TH.

THIS tent was as usual under the able and tasteful management of the Rev. J. T. Boscawen, and the general effect of the Exhibition was greatly admired, and never before have the Kent folks been treated to such a show of Orchids. The entrance was an improvement on former shows, as the local nurserymen, Messrs. George Bunyard & Co., had planted trees and shrubs, with a border of *Rhododendrons*, giving it a bright appearance; at the lower end a fine rockery was erected, and so naturally that "it looked as if it had grown there," and formed a feature in the tent. The stone used was a limestone belonging to the lower greensand formation, locally known as Kentish rag, and supplied from the Iguanodon quarries of Messrs. H. H. Bansted & Son (this firm sent a quantity to Broxbourne for Messrs. Paul's new rock garden). On entering, a prominent feature were the Orchids from D. Bain Crawshaw, Esq., of Rosefield, Sevenoaks, among which were a fine series of *Cattleya Mossiae*, examples of *C. gigas*, *C. Mendelli* and *Warnerii*, a fine variety of the latter having flowers 9 inches across, the corolla being very wide; the central plant was a grand *Odontoglossum vexillarium* with fifty flowers. Other fine examples being *Epidendrum vitellinum majus*, *Masdevallias Harryana*, *Chimæra*, and *H. lilacina*; *Phalænopsis grandiflora* fine,

Oncidium ampliatum majus, *Dendrobium chrysotoxum* and *Bensoniæ*; and *O. Pescatorei* with forty flowers. Altogether a grand group.

Another group of Orchids was sent from Preston Hall (Henry A. Brassey, Esq., M.P.; Mr. Waterman, gardener), who also sent a set of the finest *Marguerites* we have seen, perfect globes of flower. The best examples among the Orchids were a pair of *O. vexillarium*, a pair of *Vanda suavis*, *Aerides odorata* and *Lobbi*, *Dendrobium suavisimum*, and *Lælia purpurata*.

G. Ashley Dodd, Esq., Surrenden Park (Mr. Wilson, gardener), sent some grand specimens of Palms—*Phoenix reclinata* and *Cocos Weddelliana* being very large; a fine pair of *Crotons*, and a large well-flowered *Erica Cavendishiana* being among his exhibits.

G. A. Spottiswoode, Esq., Coombe Bank (Mr. Bolton, gardener), enriched the Show with well-grown examples of *Latania borbonica*, a *Kentia*, a pair of *Statice*s, large *Dicksonia squarrosa*, *Areca Verschoffeltii*, *Cycas revoluta*, and an *Anthurium Schertzerianum* carrying many fine spathes.

Roger Leigh, Esq., Barham Court (Mr. Haycock, gardener), sent some very large Palms, among which *Chamærops excelsa*, *Seaforthia*, and *Cordyline indivisa* were conspicuous, and gave great character to the Show.

Fig. 105.—*Calochortus Benthami*.

From Linton Park (Mr. McKenzie, gardener) came a large number of *Dracænas*, Palms, Ferns, &c., all exhibiting high culture.

James Whatman, Esq. (Mr. Maclean, gardener), sent some useful Palms, Ferns, and *Gloxinias*.

W. E. Brymer, Esq., M.P., Dorchester, had entered for the Orchid prizes, but at the time of reporting they had not arrived; but no doubt the winner at the Botanic would be hard to beat.

Among the trade groups the most interesting lot came from the Colchester New Plant Company, Japanese Maples being among the most numerous. In this lot we noticed some curious combination plants with many kinds on one stem, *Acer palmatum aureum* (lately certificated), *A. p. dissectum ornatum*, *rubro-marginatum*, *pictum marmoratum*, *seven-lobed sanguineum*. A large number of these were also used as top specimens for the rockery, where, owing to the light and position, their beauty could not be seen to advantage. Among the Company's Orchids was a grand *Cattleya Mossiæ* with thirty flowers, *Hystrix luteo-purpureum*, and *Odontoglossums vexillarium* and *Alexandræ* in fine varieties. The same firm showed a fine lot of *Cypripedium spectabile*, which is there found easy of pot culture.

Messrs. J. Laing & Co., Forest Hill, S.E., sent an effective group of *Begonias*. Among the doubles *The Duke*, orange-scarlet; *Prince of Wales*, vivid velvety crimson; *Mrs. Brissenden*, rose, were conspicuous. The single flowers were very large, the seedlings being nearly equal to the named

sorts, *Lady Chesterfield*, *Marchioness of Bute*, *Ball of Fire*, and *Snowflake* being the best.

Messrs. Richard Smith & Co., Worcester, sent a group of *Clematis*, globe-trained, the best being *Madame Desfosse*, white, and *Duke of Norfolk*, lavender.

Messrs. George Bunyard & Co. of Maidstone staged a group of market *Pelargoniums*, *Volonté Nationale*, *Ida*, *St. Mandé*, and *Lady Isabel* being conspicuous; also plants of the new purple-leaved *Prunus Pissardii*, which is a telling plant. The same firm sent rock plants in variety, which added greatly to the effect of this group. We also noted some grand examples of *Adiantum farleyense*, and a well-grown *Asparagus plumosus*, the owners' names not being upon them.

Prizes were given for Orchids, fruit, and vegetables, but at the time of reporting they were not awarded.

The Exhibition is held about a mile from the town of Maidstone, and commands charming views of the Medway valley, the Backbone of Kent (*Blue Bell Hill*) and the *Detling hills* being conspicuous in the background. The Show was largely patronised on the opening day.

EXHIBITING CARNATIONS.

I BEG to say, in reply to "Onwards" on page 419, and as one of those who may be classed as a large grower, that I never exhibited a flower, plant, or fruit that I did not grow; and further, that I never gave, lent, or sold a plant, flower, or fruit to anyone else to exhibit. I have no knowledge that it has ever been done at any of the shows of the National Societies, and as one of the Honorary Secretaries I have a right to more definite information. I trust that whatever knowledge "Onwards" possesses of this matter he will allow it to be utilised to hunt up the real offender, if there is one. I am sure the Editor will feel with me that to allow such an imputation to rest upon a Society that calls itself "National" would be a very grave misfortune indeed.—J. DOUGLAS.

[We are quite satisfied that our correspondent "Onwards" has no object but eliciting truth. He is, as his letter suggests, desirous of seeing floral societies flourish and made acceptable to the greatest possible number of exhibitors, large and small.]

CALOCHORTUS BENTHAMII.

For this beautiful little Californian bulb Mr. T. S. Ware, Tottenham, was recently awarded a certificate at one of the Royal Horticultural Society's meetings. It is somewhat nearly related to *C. pulchellus*, but is distinguished by its bright yellow flowers, upon the upper surface of the divisions of which are thickly clustered a number of short yellow hairs. It is very dwarf, seldom exceeding 8 inches in height, but is free both in flowering and growth. It is particularly well adapted for culture in pots, and with the protection of a cool frame it develops its flowers early in the year, and is much better than when grown in the open border. The species is a native of the Sierra Nevada near Mariposa, and has only been in cultivation in England for six or seven years, so that it is as yet comparatively unknown. Another pretty companion for the above is *C. Maweanus*, which has bluish purple flowers about the same size as *C. Benthami*, and of similar habit. This is, however, found near the coast, and in the neighbourhood of San Francisco.

PLANT CLEANING.

In all gardens where plants are grown largely the time and labour required to keep them clear of insects is enormous; but stove plants need the most attention, because insects multiply with greater rapidity in heated than in cool structures. I have had every opportunity of testing many different systems of eradicating these pests, but the majority of them have proved unsuccessful, and resulted only in keeping the insects in check and the occupants of the houses in a presentable condition. This state of things is not always due to insufficient labour, as many suppose, but because some system is not perseveringly followed. Plant-cleaning in many gardens is performed in such a way that it has to be done again at intervals of a few weeks. In many places the method practised is to select the worst plants, and after they are cleaned and returned to their former positions they soon again become infested. Another system is to allot to one man a certain number of plants, say the *Crotons*, while another does the *Ixoras* and *Gardenias*, and so on, and it not unfrequently happens that by the time a man has "gone over" the plants apportioned to him the first plants cleaned are as bad as ever, and must be done again.

Continually sponging plants to keep them clean is wrong, even if the solution used for the purpose was strong enough to kill the insects, but in many instances it is not. Instead of proving an advantage it is often, in the end, injurious to the plants, as it is almost impossible for the most careful man to carry out this operation without injury to the foliage. Careless plant-cleaning not only brings insecticides capable of doing their work, if properly applied, into bad repute, but occasions double

the labour that is really needed. There is no necessity for half the plant-sponging now practised in gardens, if only some reliable insecticide were judiciously employed.

There is no insecticide capable of cleaning plants thoroughly of scale and bug by one application without injury to the plants, not even petroleum, which is the most effectual insect-killer. If petroleum be used, say at the rate of 1 oz. to the gallon of water, well mixed in the way described so many times in these pages, this solution will kill scale and bug if the plants are thoroughly syringed. Bug is the most difficult to destroy, because whatever solution is used it runs off the insects, and they can only be destroyed by syringing the solution upon them with force. With the greatest care in syringing the plants over a vessel containing the wash some will be left, and also the old brown scale that forms the covering to the next generation. Suppose the house is filled with Gardenias. Every plant must be done, and then the house well syringed with the same solution or a little stronger. After syringing with petroleum and water it is necessary to shade the plants from the sun until the oil has evaporated. It must be understood that the plants are not to be allowed to be badly infested again before they are syringed the second time. On the contrary, directly young insects are visible, whether bug or scale, they should be thoroughly attended to. This should be repeated until the whole are destroyed. It may be necessary to syringe the plants half a dozen times at intervals of a few weeks, but it is better to do this and have the plants and houses clean than to be sponging them for years. If the stove contains a mixed collection of plants, the Ferns or any other tender-foliaged plants that will not bear such a strong solution should be placed by themselves and given a weaker solution, but every plant that will bear it should be treated the same as the Gardenias.

To show that the system recommended will prove effectual if properly applied and followed up from time to time as the insects appear, my method of clearing a vinery from mealy bug may be briefly related. After the fruit was cut the Vines were syringed with a mixture of petroleum and water, at the rate of 1½ oz. of oil to the gallon of water, every part of the house as well as the Vines being thoroughly soaked. This operation was repeated four times, the last after the Vines were pruned, and this season, so far, we have not found a trace of bug. From this treatment, however, Orchids must be exempted.

Petroleum may not prove the safest insecticide in the hands of the inexperienced, for if not applied with caution irreparable injury might result. Fir-tree oil is a reliable insecticide, and if used at the rate recommended by the makers it will effect the same result as the petroleum. There are other good mixtures sold for the purpose which are preferred by some people, and if used on the same principle will effect the destruction of such pests that infest our plants.

The softsoap mixture as a preventive against mildew on Roses, recommended by me frequently in these pages, is ineffectual if the plants are allowed to become infested before it is applied, but if used when the plants are clean they are easily kept clean with fine dark glossy foliage. It is exactly the same with stove plants when they are badly infested. They require constant attention and strong measures to clean them; but when once clean, weak solutions applied occasionally or daily, mixed with the water when syringing the plants, will act as a good preventive.—N. G.

KITCHEN GARDEN.

JUNE is generally a satisfactory month in the kitchen garden, as work is not very pressing, and valuable returns for winter and spring expenditure are forthcoming in the form of many delicious young vegetables. We have now plenty of new Potatoes, Peas, Cabbage, Turnips, Carrots, Globe Artichokes, Asparagus, &c., with an abundance of all kinds of salading, and these never fail to give satisfaction in the kitchen at this season. The supply, however, must not be temporary where the demand is constant, and operations of sowing, planting, and cultivating must go on unceasingly.

Runner Beans.—Earth up those now well above the soil, and then stake them. Stakes are not always readily obtained. They ought to be from 6 feet to 8 feet high, but where such cannot be had shorter ones must do, and these may be 3 feet or so. In their case the runners may be topped when they reach the proper height, continuing the process as often as is

needed. Sow another row to succeed those put in some time ago. The only way of securing a good supply of pods until November is to sow in succession until the end of June.

Broad Beans.—The earliest of these are now nearly ready, and in cases where they are behind the tops should be nipped out of every stem above a few of the clusters of flowers. This will make them pod immediately, and any which show a disposition to become too tall or top-heavy should be treated in like manner. Sow a succession of any free-bearing sort. Strong rich soil is the most suitable for them.

Earthing-up Celery.—Where the early plants are growing fast and assuming large proportions they should be earthed-up. This operation cannot be too carefully performed. If the soil is allowed to go into the centres of the plants at the first earthing they will be spoiled. To begin with, the smallest of the outside leaves which cluster round the bottom of each plant should be drawn off, then a piece of matting tied round each plant will hold it together until the soil is put round, when the tie can be taken off again. The earth should not be thrown roughly against the plants, but broken up very fine, pressing it against the plants with the hands. A depth of 4 inches is generally enough to place against them at one time. Sow a pinch of Celery seed in a favourable spot in the open to supply plants for a late batch. Water all Celery copiously in very dry weather.

Radish.—Sow in the coolest corner of the garden. Too thick sowing is a great and common mistake with Radishes. When the plants are so close to each other three parts of them have no room to develop, and they are consequently lost. Avoid this.

Spring Cabbages which have been cut may be treated in two ways. One is to allow them to remain, and in six weeks or two months they will have formed many useful side heads; the other is to pull the stumps up and occupy the ground with another crop. Both ways are good, and we leave cultivators to choose between them.

Onions.—Autumn-sown Tripolis and others which are showing flower stems should have these pinched off. They will then bulb more freely, and although they may not become so large as those which have not "bolted" they will prove useful, and should be pulled up first, leaving the best plants to make large bulbs. Where spring-sown Onions have failed here and there in the rows thin them out from the parts where they are growing close, and make up the blanks in the rows. If this is done when the soil is wet or on a wet day there is no danger of any failing to grow. Last year some of our best bulbs in the autumn were the produce of plants dibbled in during the latter part of May and early in June.

Globe Artichokes.—As the heads of these become large enough for use cut them at once, as they lose their value when old, and, worse still, they hinder the young heads from swelling so freely as they would do if not checked.

Tomatoes recently planted in the open should have plenty of clean water when the weather is dry. Stop all side shoots, and keep the main stem constantly secured to the wall or trellis.

When rain occurs take the favourable opportunity of planting out Broccoli, Savoys, Brussels Sprouts, &c. Throughout the season look out for any vegetable showing a distinct type and improved form. Mark it and save for seed. Hand-weed between and amongst close-growing seedlings and hoe the open spaces.

FRUIT FORCING.

VINES.—Early Forced House.—When the early Vines have been cleared of the fruit afford a thorough supply of tepid liquid manure to the inside borders, and syringe daily thoroughly until the foliage is cleaned from all accumulations of dust and insects. The ventilators may remain constantly open. When the Vines commence making fresh laterals maintain an even growth by pinching out the points of those laterals that grow too vigorously, and so prevent their depriving the weak parts of the nutriment essential to the proper development of the buds that are to give next year's crop.

Houses with Ripe Fruit.—Keep cool, ventilating freely, and a double thickness of herring nets placed over the roof lights will do much to keep Hamburgs from losing colour, as they often do when exposed to powerful sun over a lengthened period. Keep the laterals closely pinched, not allowing them to crowd the principal foliage, which it is important to keep clean and healthy to the last. A moderate amount of moisture in the house will not injure the Grapes at this season, and is absolutely essential for the benefit of the foliage; hence the borders and other available surfaces may be sprinkled in the morning of fine days, and with proper ventilation there will not be any damage from the moisture to the Grapes.

Houses with the Grapes Ripening.—When the Grapes commence colouring, both the outside and inside borders should be given a thorough soaking with tepid liquid manure, then mulched with short manure, and this will be sufficient in most instances to carry the fruit to maturity. If the weather be wet it will not, of course, be necessary to water the outside border. Keep a good moisture in the house by damping available surfaces in the morning, and again in the afternoon if the weather be bright, as the Grapes swell considerably in ripening, and keep a gentle warmth in the pipes so as to admit of a circulation of air constantly. A temperature of 80° to 85° should be secured during the day with sun, and 70° to 75° without, allowing the temperature to fall to 65° (or even to 60° if the Vines are carrying heavy crops) through the night. As the Grapes advance in ripening lessen the atmospheric moisture, but avoid a parchingly dry atmosphere, or the foliage will be seriously damaged to the prejudice of next year's crop.

Vines Swelling off their Crops.—Allow as much extension of the laterals as the space admits without crowding the principal foliage, and

admit air early in the day, increasing it with the solar heat, maintaining the temperature at 80° to 85° through the day, closing early in the afternoon with plenty of moisture in the house, and damping the floors and borders with guano or liquid manure before nightfall. Fire heat will only be necessary to maintain a day temperature of 70° to 75°, and to prevent it falling below 65° at night. Give tepid liquid manure copiously to the inside borders, and outside as well if the weather be dry, mulching both with short sweetened manure.

Late Houses.—The late-keeping Grapes ought to be set by this time, and as they swell rapidly at this season the thinning must be attended to without delay. Make choice of medium-sized tapering bunches, and thin them rather more severely than those not required for hanging through the winter. Lady Downe's, Muscats, and others liable to scald when passing through the stoning process must be closely attended to, the best preventive being keeping the houses warm at night to prevent condensation of moisture on the berries, and freely ventilating in the early part of the day to avoid a sudden rise of temperature.

Melons.—Where these are esteemed a good late summer supply can be obtained by utilising the pits and frames that have been employed for hardening off bedding plants. It is better to make up a slight hotbed; but this is not absolutely essential, as with the frames stood in a warm position with a southern exposure, and a barrowful of soil in each light, Melons will do capitally. The soil should be strong, and may be made porous by adding a fourth or sixth of lime rubbish. Tread firmly and keep the frames close for a day or two, so that the sun may warm the soil, and insert a strong plant in the centre of each light. Should the weather be bright shade for a few days, and beyond giving a good watering when planting none will be required for some time; but the bed and plants will need syringing every afternoon on fine days at closing time, or from 3 to 4 P.M., and air will need to be given early, or from seven to eight o'clock in the morning. The time, however, of giving and taking off the air will need to be regulated by the weather. Houses in which the fruits are approaching maturity should be ventilated freely, and a rather high and dry atmosphere maintained. Attend to stopping, tying, thinning, and otherwise regulating the growths in other departments. Impregnate the flowers daily, and where the fruit is set use the syringe freely twice a day when the weather is bright as a preventive of red spider.

Cucumbers.—In successional houses, pits, and frames attend regularly and frequently to the stopping, thinning, tying, and regulation of the shoots, removing old growths, so as to make place for new, and cutting off all superfluous and badly shaped fruit. Maintain a steady bottom heat and an equable temperature; sudden checks whilst the fruit is swelling will probably result in deformed, badly swelled, and ill-flavoured fruit. Plants that have been in bearing some time should have a top-dressing of three parts loam and one of decayed manure, giving tepid water, and when the roots are working freely in the fresh soil mulch with a couple of inches thickness of well-decomposed manure. Thin the shoots well out and encourage fresh growth in their place. Syringe twice a day during favourable weather, and close as early as is safe in the afternoon, so as to make the most of the sun's heat.

PLANT HOUSES.

Epacris.—Plants cut back and placed in heat or a close structure have started freely into growth, and should be removed into cold frames. If left too long in a close atmosphere after they have commenced active growth they soon draw up weakly, which is detrimental to their well-being. After they are first placed in frames they must be carefully and gradually prepared for more airy conditions, but this must not be done at once or the plants will be checked. Repotting where required must be completed, and the plants treated afterwards with care until they are rooting freely in the new soil. Those that do not need potting may now have an application of artificial manure. These plants must be watered with great care, never allowing them to suffer from an insufficient supply, or their fine roots will soon be injured. Light shade should be applied during bright weather, but only sufficient to break the full force of the sun. Syringe the plants twice daily, and close the frame early in the afternoon while the sun is upon it.

Winter-flowering Heaths.—The early-flowering varieties will now be growing vigorously, and should have abundance of air during the day, and when very mild a little may be left on all night. During bright weather and drying winds it is much better to keep the frames moderately close and shade liberally instead of admitting air. This prevents the plants drying too quickly, which soon proves injurious, the foliage turning brown and falling. These plants must not be crowded together, but should have plenty of room to develop. Those rooting freely and growing vigorously may have abundance of water from the present time.

Summer-flowering Heaths.—These are much better in pits and frames if they are not too large for such positions than in warm dry houses. They should stand upon some moisture-holding material, and if possible should occupy a glass structure with a northern aspect in which the atmosphere at this season can be kept more suitable for them. When grown in this position less shading is required. If the plants are grown in a southern aspect the strong sun only should be screened from them.

Cinerarias.—The plants from the earliest-sown seed are now in 3-inch pots. After potting they should stand upon ashes in a cold frame where they will receive abundance of light, and yet be shaded from strong sun. Pot these plants from time to time as they require it in good loam, with a third of leaf mould and manure, and sufficient sand to make the whole porous. Watch for aphides, and if they appear fumigate the plants. Water liberally when the plants are growing freely, and give them abundance of air. Prick out later seedlings into small pots and

grow them under cool treatment. Another pinch of seed should be sown and the pan stood in a cold frame.

Celosias.—The earliest plants are now bearing some fine plumes of flowers, and can be removed to the conservatory if wanted there. They will scarcely have attained to their full beauty, but are sufficiently showy for that structure, but should not be crowded amongst other flowering plants, or their full development will be impeded. Succession plants will be ready for 6-inch pots—a suitable size for decoration, and should be grown under cool treatment. No artificial heat will be needed from this date, but the frame or house in which they are grown should be closed early in the afternoon when the plants are syringed. Red spider is the greatest enemy to these plants, and they must be syringed freely. Plants in the seed pan should be placed in small pots when large enough, and be brought on gradually. A little more seed can be sown to yield a supply of plants for the conservatory from November to the end of January, and another pinch of seed a fortnight later for affording plants for growing in small pots.

THE FLOWER GARDEN AND PLEASURE GROUND.

Roses.—Where the quality of the blooms is of more importance than the quantity, a considerable amount of thinning-out the growths at the present time, and the buds later on, is necessary. Every shoot reserved should have room to develop, and as a rule the greater portion of the inside buds should be rubbed out. The thinning, however, should be gradually performed, as if only a few shoots are retained in the first instance there will be none to replace any that may be damaged by the grubs or caterpillars. Wherever any of the latter are found enrolled in the young leaves they must at once be destroyed, or the points of the shoots will quickly be eaten. Hand-picking is the best and only sure remedy for getting rid of these troublesome pests. Aphides are also very prevalent this season, and these also should be destroyed as much as possible, nothing being better for the purpose than tobacco water freely diluted according to its previously ascertained strength, and syringed over the plants occasionally, and preferably in the evenings. A decoction made by boiling 1 lb. of quassia chips and 2 lbs. of soft soap in a gallon of water for an hour, and then strained off, will also be found serviceable for the destruction of both mildew and aphides on Roses. This also should be used according to its ascertained strength, but as a rule one pint added to four gallons of soft water will usually be found strong enough, and it should be frequently syringed over the plants. Autumn-struck Roses should not be lifted in any way, but the ground about them may well be lightly hoed and a mulching of short manure given them. Support the strong young growths forming of last season's budded Briars, or a heavy wind will blow them out; also keep the shoots on the Briars or stems closely rubbed off, and the suckers pulled away. Thin-out the shoots on the Briars to be budded this season, leaving two or three, according to the vigour of each, evenly disposed near to the height required for the future head.

Planting Flower Beds.—By the time this is in print bedding-out will be considerably advanced in the majority of gardens. Those beds previously occupied by spring-flowering plants will this season be very dry and much impoverished, and unless freely manured will not suit many of the summer occupants. A good soaking of liquid manure will also do much good, both before planting and subsequently when the plants are well established. We prefer to plant during showery weather, but if it is necessary to proceed during very dry hot weather, as at present, the surface of the beds are watered a few hours prior to planting, this enabling us to thoroughly break-up the soil. The roots of all plants, whether in pots or transplanted from frames, should be in a moist state when planted, as if dry the greatest difficulty will be experienced in moistening them again, and unless this is done the start will be very slow. Plant very slightly below the level, well work the trowel round the roots, and fix them firmly. If a slight basin is formed round the stem of each plant they can be kept more easily moistened during dry weather, and when the plants are well established the surface may be levelled either after a soaking rain or a good watering. Where the plants are kept pegged down, and which is necessary if a flat and neat surface of colour is required, they should be planted in a sloping direction, this admitting of their being safely and evenly spread over the ground. The outer lines or edgings should be first planted, the remainder of the beds being afterwards filled in. For long straight borders use the garden line, and for the principal circles and lines near the edges of beds mark the places for these with either large wooden compasses or with the back of a rake, as it is a mistake to attempt to plant quickly and neatly without some kind of guide.

Styles of Planting.—Where there is a large expanse of turf, with perhaps heavy backgrounds of trees and shrubs, the beds cannot well be made too gay, but a number of beds filled with masses of bright colours are by no means suitable for small lighter places. In the former case masses of one kind of Pelargoniums, Heliotropes, or Verbenas, edged with a broad band of such plants as Lobelias, Ageratum, Pyrethrums, Alyssum, Cineraria maritima, and Ivy-leaf Pelargoniums are the most effective. Mixtures are pleasing and appropriate in any garden. The centres of large beds filled with a mixture of purple Violas and Silver, Golden, or Bronze Pelargoniums; Silver-variegated Pelargoniums and Verhena venosa or V. Purple King; pink-flowering Pelargoniums or Iresine Herbstii and yellow Violas; white Verbenas or Cineraria maritima and Salvia patens; white or yellow Marguerites and single Petunias or seedling Verbenas; Iresine Lindenii and Gazania splendens; Mrs. Pollock or some other Golden or Silver Tricolor Pelargoniums and seedling blue Lobelias; Tuberous-rooted Begonias and Mesembryan-

themum cordifolium variegatum, all with suitable edgings, are worthy of a trial. Subtropical plants are suitable either for massing or for mixing with any of the above-mentioned kinds, but as most of them are easily injured by cold they should be the last to be planted. Rather, however, than they should become stunted and root-bound a small shift or a rich top-dressing should be given.

THE BEE-KEEPER.

THE SEASON—SWARMING AND SUPERING.

So far this year the bees have had a hard struggle to exist. The year opened favourably on them with less mortality than ever I experienced. Large patches of brood were in every hive during January, and breeding was unremittingly carried on throughout the cold winds of that month. Many young bees were flying in February. Flowers and sunshine came with March, and good hives collected much pollen from the Crocuses, Willows, Tussilago, &c. Many hives were then advancing rapidly, and were well forward, promising early swarms. April we welcomed, but it brought thunder, snow, and frost of unusual severity—bleak cold weather, with scarcely a ray of sunshine to gladden us. This lasted until 23rd May. Flowers had almost disappeared; those not destroyed looked sickly, and dead bees strewn every path. Hives that looked like swarming seven weeks ago have made no progress, while many that by this time with mild weather would have been strong are so reduced in bees that they will be unable to do more than keep themselves alive. Our locality is, however, not a sheltered one; there is a paucity of trees in the district, arising through proprietors of small estates cutting down every tree that can be turned into cash, and the ground they occupied made available for cultivation.

In more sheltered places the bees had a better opportunity of making progress, not from the mere shelter alone, but from getting the advantage of the flowers sheltered and preserved by the trees, which also many of them yield large quantities of honey and pollen. While our bees in an unsheltered district have been much checked and retarded, those in sheltered situations have advanced, and swarming commenced at Crossford near Carlisle in the beginning of May, but the weather since then and until the 23rd of May, when a favourable change took place, was very untoward. With fine weather now the bees from their contiguity to plenty of fruit and Sycamore blossoms will make rapid progress, and if the apiarian is careful to sustain the breeding in rainy weather these early swarms, with the further advantage of the Charlock, Clover, or Heather harvests may rise to a great weight; indeed, I have known such swarms, including the old stock and the second swarm, to rise at the end of the season to 600 lbs. It is under such favourable conditions that early swarming takes place, which makes the swarming system so profitable. In later districts, such as where I reside and where swarming is much later, it is impossible to have swarming hives crowded with bees in time to attain such results, hence the reason we have to carry out the non-swarming system to the extent we do; in fact, though we get early swarms, they, from the paucity of flowers, the trouble and expense of feeding, with loss of bee life resulting therefrom, would be greater than any profit that could be made.

Under the swarming system the greater portion of the honey must be dripped, while under the non-swarming system the surplus is obtained from supers in its purest form, but under either system in wooden or straw hives the most proper and profitable course to pursue for honey in any form is to extend the hive vertically. The circle is the natural form in which bees cluster and carry on the internal economy of the hive. Whenever that form is departed from to the oblong the bees are handicapped, working at a disadvantage, with less profit to the owner. I have seen a number of instances where bees stored honey 3 feet from their hive, and "R. S." had a bellglass finished in a like manner, but though bees do this in a warm season it is no argument in its favour. We avoid inducing bees to work by feeding at any time when they should be kept quiet, but when the weather is favourable for honey-gathering we never allow them to relax work, and we assist them as much as possible. In a proper hive, of which the Stewarton may be taken as a type, the bees are enabled to keep up the degree of heat necessary for the secretion of wax and comb-building, even though the temperature becomes low at night or at any time. With plenty of newly built comb the bees are ready for the collection of honey when it is secreted in the flowers, hence the quantity stored in such hives is greater than in those of an oblong shape, when, on the temperature becoming low in such hives, bees cease to secrete wax and build comb, retreating at night from their labour, then in the morning resume comb-building, while those on the Stewarton principle are rapidly filling their night-made comb with honey. The greatest harvests of honey

recorded are from those wrought on the vertical principle—for example, S. Bevan Fox with his telescope supers, and "A Renfrewshire Bee-keeper" with 200 lbs. at one lift of pure super comb from one hive, and many others equally successful, including myself, with the same kind of hives. While, however, I give my approval of this system, I by no means wish to discourage other systems, because many hives can be cleared from objectionable points they may possess.

With a few remarks on supering I will close this article. It is a fact that bees naturally incline to ascend to supers rather than work laterally. They also store more honey in proportion in large supers than in small ones. There, again, the Stewarton comes to the front; no matter how many supers there be they act as one, while all are divisible to a comb. Sections are preferred by many, but I think they have had their day. I find the bees do not take to them so readily as supers from the obstructionable bottom of the section, then in most cases a cover of sections over a hive are in three. In my own case I work sections (no matter how many) in one compartment, beginning with few and increasing the number as required. It is accomplished as follows:—I place frames, minus the top bar, in a case the same size as the hive, which is supplied with a dividing board. These frame ends have a ledge to keep the sections in position, and the bottom rail of the frame has staples or tin clips bent to form a ledge for the same purpose. The sections are of only $1\frac{3}{4}$ inch broad, and require no rattle to admit bees from one to another; the one-eighth ledge on a frame answers this purpose. The above plan is not only better to secure a greater amount of honey, but is much easier manipulated and inspected than when placed in crates; but sections are not generally in favour, neither with bee-keepers nor honey merchants, so far as I have experienced. Upwards of a hundred bee-keepers that I spoke to on the subject last year, and who had tried them, were against them, but whether sections or supers are used the bees should be admitted to them from the outside combs only. If the crown of the hive is not fitted with sides of some sort thin adapting boards should be used, so that the centre of the hive over the brood be closed to prevent discoloration of combs, or queen ascending, or brood being chilled when cold weather comes. Supers should have ample coverings to prevent the escape of heat. When bees are filling supers they should never be disturbed, unless when actually necessary to do so, and when it is warm and the sun shining, for then bees are less inclined to sting than when it is cold. When one super is filled with comb another should be added above. This keeps the bees better employed at comb-building, and relieves the overcrowded first super.—A LANARKSHIRE BEE-KEEPER.

CYPRIONS, SYRIANS, AND FOUL BROOD.

"J. P. S." (pages 392-3) says, "Cyprians cannot be handled with smoke any better than Syrians." Quite so; neither must they even smell it or be jarred. If these precautions are taken and opened when the sun shines they will be found second only to Syrians in tameness, to which bees they are nearly allied. Those who condemn the Syrians and Cyprians for their savageness have used smoke to them or else they have not had the pure races. Mr. Doolittle in the *American Bee Journal*, quoted by a correspondent a short time ago, page 132, says, "As Mr. Carroll wrote me that I should have less difficulty in handling the Cyprians if I used no smoke, I placed the smoker well filled and lighted on the top of the next hive, and proceeded to carefully raise the quilt," and then, of course, he found them quite savage. I give this quotation to show that people should follow the directions given by those who know. Mr. Benton in Cyprus had 500 colonies placed round his house, on the verandah, or anywhere where they could stand. One hive in particular was so placed that it had to be passed within 2 feet from the entrance scores of times each day by every visitor or inmate; and though Mr. Benton was working amongst them from early morning to late at night with no protection whatever save a hat, shirt, pants, and slippers, no one was ever stung, and he very rarely. We have Mr. Blow's authority for saying that he saw Mr. Benton open his hive after hive without veil or gloves, and none ventured to sting.

My opinion is like "J. P. S." regarding foul brood—viz., that it will attack hives in a certain condition more readily than others, just as a dead sheep will breed maggots more readily than a live one, though they will not breed spontaneously in either; but I must disagree with him when he says they are liable to it when in a dysenteric condition. Neither do I believe these new races of bees are more liable to it than others. It is not everyone who can discern this disease, as I have myself seen an expert and one who has had the disease in his own apiary mistaken.

These eastern bees rear an immense amount of brood and pack it in a solid mass, and, what is more, they require a greater degree of heat than blacks to develop it, the critical time being the transition stage from the larva to the pupa state; therefore the slightest chill by opening them on a cold day will cause the brood to die, which looks like and is taken by most people for foul brood. A damp cold hive will also cause it; hence these bees must always be crowded together. On no account must brood be spread or divided with empty combs or frames. Hives should be dry, warm, double-walled, with dry porous quilts on the top; and they should never be opened except on a warm day when the sun

shines, and this should be done as early in the day as possible, so that the hive may regain its heat before the evening is cool.

If by any chance you get this so-called foul, or rather chilled brood, the best way to deal with it is to put it into a queenless colony for all the live bees to hatch out; then with a sharp knife shave off the caps, dust well with powdered charcoal and hang up to dry, when they may be again used with impunity. These bees in the wing state will stand greater cold and punishment than our native blacks owing to their greater vitality, but the brood will not. Probably this may be accounted for if we remember these bees come from a warmer climate.

Let me be distinctly understood that I am not a race-worshipper. Bees have no attractions for me if they will not yield any honey, no matter how beautiful or ornamental they may be. The "Lanarkshire Bee-keeper" is taking a step in the right direction by crossing Cyprian queens with Ligurian drones, and the produce with Carniolian drones. It is only by crossing these foreign bees that we may hope to produce superior varieties. It has been done in every other branch of the animal and vegetable kingdoms, and why not with bees? for with all their virtues—which should make us more anxious to improve them—they are only wild bees we are cultivating at present. Cyprus gave us the Cauliflower, and who would recognise the original in the immense varieties of Broccoli and Cauliflower, or would banish it from our gardens? and may not one or all of these bees produce a breed of bees as distinct and valuable to the present as the Magnum Bonum Potato is to its first parents? Let us go about this matter in an intelligent manner, each adding his mite; and for the present those who want a good crop of honey and plenty of bees in the spring to fertilise their abundant fruit blossom, I would advise such to try the first cross of Syrians with pure black drones.—HALLAMSHIRE.

TRADE CATALOGUES RECEIVED.

Paul & Son, Cheshunt.—*Catalogue of Hardy Herbaceous Plants.*
Ant. Roozen & Son, Overveen, Haarlem, Holland.—*Catalogue of Dutch and Cape Bulbs.*
W. Lovell & Son, Driffield, Yorkshire.—*Select List of Strawberry Plants.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Brighton Show (Exhibitor).—Letters such as you have sent should be accompanied by the name and address of the writers, and if you will forward yours, not for publication against your desire, the advisability of inserting your communication shall be considered.

Child's Hill, Hampstead, Horticultural Society (J. B.).—The Secretary last year was, we believe, Mr. Williams, The Gardens, Frognaal Rise, Hampstead, and we have not heard of any change in the Society's officials.

National Rose Catalogue (Young Gardener).—If you write to the Rev. H. H. D'Ombra, Westwell Vicarage, Ashford, Kent, enclosing a stamped directed envelope for reply, you will obtain the information you need. You are in error on the other subject. No pamphlet is published by the gardener you name, and consequently has not been referred to in the Journal.

Pteris serrulata cristata major (W. M., Liverpool).—We received from you about ten days ago what appears to be a frond of this fine Fern, but the announced "particulars by post" have not yet reached our hands.

Market Gardening (Student).—We suspect you will find it difficult to get into such a garden as you have in view unless you have someone who is acquainted with the proprietor willing to recommend you to him. Numbers of students would be glad to have a term in some of the establishments in question, pay a premium for the privilege of entrance, and receive no wages for a year. The alternative plan is to get in as a labourer, and with such a position you would possibly be disappointed.

Insects Found in a Church (H. M.).—The specimen sent is a species of beetle, *Anobium striatum*, one of those that live in wood, and which has doubtless a colony in the woodwork of some of the old pews. To this, and to others of the same family, the ominous name of "death watch" has been given, because our superstitious ancestors believed the noise they made when heard in a house was a sign of the approaching death of an inmate. This beetle first appears as a six-legged larva or grub, which also resides in the

wood on which it feeds, and, like the beetle, it is believed to produce a sound by striking its head against the sides of the burrow it has cut, with the object perhaps, of ascertaining how near it is to the outer air. Made by the mature beetle the sound is supposed to be a call from one to the other, but this must be deemed doubtful, their history being insufficiently known as yet.

Myosotis dissitiflora (L. Thompson).—You may remove the plants when you like after they cease to be attractive, and plant them in a cool moist position on the north side of a wall. They may be laid in closely together and rather deeply, and if kept constantly moist they will in a short time commence growing, and roots will be emitted from the stems. In showery weather in August the plants may be divided, and the rooted portions inserted 9 inches apart in rich soil, watered as needed to keep them growing, and fine plants will be had for flowering next spring.

Taking up Crocuses (Boelfre).—The Crocus bulbs, of which you sent specimens with "grass," are taken up too soon, as the bulbs are not nearly full-sized, and have no skin, the grass being very green and fleshy. It is not necessary to let the grass die down before lifting the bulbs, but when it begins to turn yellow the bulbs may then safely be lifted. We usually lift ours in beds at the close of May so as to make way for bedding plants, but we find such are not nearly so good in flowering the following spring as those that are allowed to mature their growth before lifting, and those that are not disturbed at all are very much the best.

Pelargonium Leaves Turning Yellow (Oldham).—It is evident there is something in the atmosphere of your houses that is not suitable for plant growth, and may arise from the vapour pouring out of the "hundreds of mill chimneys" in your locality. We, however, passed many years in a smoky locality, but the atmosphere did not produce such a state of things as your specimens indicate. They are simply dried up, a result, we think, of too dry an atmosphere, which may have been accelerated by the fumes from the mill chimneys, especially as the wind was strong, and would no doubt enter the house by the ventilators. In such weather we found it best to keep the floors frequently damped, and admit no more air than was absolutely necessary to prevent the temperature becoming dangerously high, and breaking the force of the in-draught by some wool netting over the ventilators. The netting with quarter-inch mesh answered perfectly, and it was kept on constantly so as to sift the air as it passed in, as it did by the wool becoming coated with sooty matter.

Cucumbers Gummy (T. J., Chester).—In all probability you have been treating the plants too generously with liquid manure, and the foliage has been unable to assimilate the abundant supply of sap. If this is not the cause of the exudation we fear your plants are attacked by the disease. Remove the worst fruits and keep the atmosphere drier, also increase the temperature; cease also the supplies of liquid manure, only giving sufficient water to keep the plants steadily growing, and note the effects of the change of treatment. *Dahlia Juarezii* is not a single variety, but double, though the florets are not cupped and incurved like the show varieties; the colour is brilliant scarlet. The colour of the other variety you name is orange yellow.

Cucumbers Flagging (B. B.).—We have little doubt as to the cause of the leaves flagging and the young fruits failing to swell. If you examine the soil at the bottom of the bed quite down to the slates over the hot-water pipes you will find the soil dry, and it will not be made moist by one or two ordinary waterings. Water must be poured in the bed copiously and repeatedly as fast as it drains away until every particle of soil is made thoroughly moist. As soon as you effect this—and it may take two or three days—you will find your plants able to withstand the sun, and the young fruits will swell freely. The surface roots to which you refer will increase under the treatment we advise, and should be covered periodically with rough rich soil; but such roots, however apparently healthy they may be, do not avail for affording Cucumbers adequate support when the soil below is dry. For a week or so slight shade may be needed, but with an abundance of active roots and abundance of water, with a judicious system of ventilation, we rarely indeed find it necessary to shade Cucumbers, however bright the weather may be.

Canterbury Bells not Flowering (Disappointed).—Your plants are not producing flower spikes because the seed was not sown soon enough by at least two months. September is quite too late for sowing for insuring good flowering spikes the following year. Seed should be sown at once in well-watered drills and lightly covered with fine soil, shading the ground with a mat for a week afterwards if the weather proves dry and the days bright. It is, perhaps, better to sow thinly in boxes of prepared soil, covered with squares of glass and well shaded for keeping the soil constantly moist. These boxes may either be stood in the open air or in a cold frame, and the seedlings when large enough transplanted in the open garden. Your plants that are too late for flowering this year will probably afford noble spikes next season. The "authority," whose advice you followed in sowing in September has evidently something to learn in raising plants of these effective and easily grown border flowers.

Vine Leaf Eaten (H. S.).—The leaf sent appears as if it had been eaten by the Vine weevil—a brown beetle-like insect that is often very destructive in vineries. These weevils feed mostly at night, and may be found by carefully searching for them with the aid of a lantern, caught, and destroyed. There is no easy method of extirpating them, but we have been told that syringing the Vines with a solution of nicotine soap at the strength of 2 ozs. to a gallon of water renders the foliage distasteful to the insects. The Fig leaf was so dried that it crumbled to pieces when removed from the box. If the tree is outdoors the young leaves may have been injured by frost, as many have in the south during the past fortnight. If it is under glass the shrivelling is probably the result of drought at the roots, or insufficient air early in the morning. The *Narcissus* is a small and highly perfumed double variety of poeticus. A larger variety is very beautiful now, and sold largely in Covent Garden and other flower markets.

Grapes Rusted (J. O., Monmouth).—You cannot do anything now to free the berries of the "rust," which has probably arisen, in part at least, from the sulphur which has been employed in destroying the mildew, and it sometimes results from syringing, which in your case ought not to be practised, as it will only aggravate the evil, and will have a tendency to cause the

berries to crack. Cease syringing the Vines, but maintain a genial moisture in the house by damping the floors and borders in the morning and again at closing time. Admit air early, and close early in the afternoon with sun heat, increasing to 85° or 90°. Avoid sharp currents through the house of cold air by moderating the ventilation in cold bright weather, as it is the sudden cooling of the skins of the berries that causes them to rust. You will do well to leave the top lights open to the extent of an inch or two all night.

Carpet Bed Design (Stafford).—Certainly you have "as much right to have suggestions for planting a square bed as another correspondent had to a round one," and we submit most readily any designs we have prepared; but we cannot undertake to sketch a method of planting for every correspondent who may desire it. The annexed design may possibly be suggestive.

Fig. 106.

It was very effective at Hampton Court planted as follows:—1, *Echeveria secunda glauca*; 2, *Mesembryanthemum cordifolium variegatum*; 3, *Antennaria tomentosa*; 4, *Alternanthera magnifica* or *A. paronychioides major*; 5, *Alternanthera paronychioides*; 6, *Herniaria saxatilis*; 7, *Alternanthera amœna*; 8, *Pachyphytum bracteosum*; 9, *Sempervivum montanum*, slightly raised and planted thickly; 10, *Alternanthera amœna*. The border lines (No. 1) are intended to be raised 4 or 5 inches, and planted with two rows of *Echeverias* and a little *Sedum glaucum* interspersed. This bed can be planted without *Echeverias* and look well, but it will have a better appearance by marking out all the small beds in the design with these useful plants. A variety of plants are suitable for No. 2, but few excel for a low yet cheerful groundwork *Mesembryanthemum cordifolium variegatum*.

Red Spider on Melons (J. T. S.).—The Melon leaf that was doubled up and enclosed in a letter arrived in such a dried and crushed state that it was of no use whatever for the purpose for which it was sent. The greenness of the leaves described is not indicative of the presence of red spider, nor ought this insect to be allowed to get established in a house where the under sides of the leaves can be syringed. Still, as those from the bed to the wires cannot well be syringed, it might be well to sponge them carefully with a mixture of sulphur and water if there are signs of the presence of the pest. With sufficient moisture in the soil and atmosphere, and care in ventilation, there ought to be no difficulty in keeping the plants healthy and

clean. The bed is quite large enough, though an inch of soil might be added with advantage and pressed down pretty firmly as roots protrude through the surface. Your treatment appears to be right, but we should prefer the night temperature 5° higher, at least the Melons would prefer it; and the top lights left open to the extent of an inch or so all night, and we should not give front air until ventilation by the top lights proved insufficient from preventing the temperature increasing above 80° to 85°. You cannot close too early in the afternoon with moisture, provided the temperature does not exceed 90° afterwards. A close atmosphere at night, especially if damp, with a temperature of 60° might induce an attack of mildew, and a more buoyant atmosphere, with a little more fire heat, would encourage the growth of the plants and facilitate the setting and swelling of the fruit.

Creosote for Hop Poles (S., Sussex).—We do not know of anything better than good creosote for dipping them in, for all is not of equal merit. Some time ago Mr. Charles Whitehead directed the attention of Hop planters in the *South Eastern Gazette* to the adulteration of creosote, of which he said samples had been analysed by Dr. Voelcker and found to be not at all suitable for the purpose of preserving wood, as they consisted largely of the heavier tar oils. Upon being subject to distillation they yielded only about 61 per cent. of volatile oils, of which only 4 per cent. were carbolic acid; while good creosote should yield quite 75 per cent. of volatile oils, containing 10 to 15 per cent. of carbolic acid. The specific gravity of the samples was 1.103, while the specific gravity of good creosote should not exceed 1.06. A few persons have had doubts for some time past as to the quality of the creosote they have received, and have thought that it has not thoroughly and properly preserved the structure of Hop poles and timber from the effects of dry rot and the influences of the weather. At least one leading agriculturist in Kent declares that he has sustained heavy losses from the impurity of creosote and its inefficient operation. All who use creosote know in what a thick and generally unsatisfactory state much of it is delivered, and how short it is frequently in quantity, but the majority of Hop planters have not suspected that it has also been wanting in respect to quality; therefore it is desirable that attention should be specially directed to this very important point, in order that buyers of creosote may protect themselves by requiring a guarantee that it is up to the proper standard of purity and efficiency.

Cytisus Adami (A. Smith, Bedale).—The above is the name of the Laburnum of which you have sent specimens. It was originally produced upwards of sixty years ago in budding *Cytisus purpureus* on the common Laburnum. In this process it is supposed that a cell of the one species became divided and united to a cell of the other, and the result has been a plant producing not only flowers of each species separately, but others partaking of the characters of both. There are other instances in the vegetable kingdom in which a similar union of cells is believed to have taken place, but *Cytisus Adami* is the best known and best established. The changes produced on the Laburnum when grafted are sometimes wonderful and wholly unaccountable. We have rarely seen the common or Scotch Laburnum sport into other varieties. We recollect only one instance in which flowers of purpurascens appeared. But if you graft either of the Laburnums with *Cytisus purpureus* or *Cytisus supinus*, the vagaries which sometimes take place are astonishing. We know of a small standard of *Cytisus alpinus* which was grafted with *Cytisus purpureus*, and on the same branch will sometimes be found small pieces of yellow and purple, and at the very point strong shoots of the *Cytisus alpinus*; the "blood" of the stock finding its way through the more weakly growth of the scion. What is remarkable is, that grafting or budding with one variety will frequently, as the plant grows, produce three or four varieties. As an example of the remarkable sportiveness of the *Cytisus Adami*, a Dutch correspondent sent us the following note a few years ago:—"Before me is a spike bearing fifteen flowers. Examining them from the base, they are arranged in the following order:—One yellow flower, two violet, one yellow, one violet, two yellow, one violet, one yellow, one violet, five yellow—a total of five violet and ten yellow flowers, and the effect is very striking."

Peaches not Stoning (Gardener).—The chief cause of the fruit not stoning is the badly ripened state of the wood the previous season, and this you must remedy before there is any probability of their stoning satisfactorily. In the current year you must keep the shoots so thin that the foliage will have full exposure to light and air, as crowding induces weakly growth and long-jointed wood, whereas it should be stout and short-jointed, with sufficient space for it to be solidified as made and to insure its ripening. As you have so much fruit falling we should thin out the growths now where they are too thick. They should be 12 inches apart to insure a proper exposure to light and air. Stop any gross growths, so as to equalise the sap and induce an equal vigour through every part of the trees. In autumn, or so soon as the leaves give indications of falling, lift the trees and lay in the roots nearer the surface in fresh compost. This is the best remedy for immaturity of wood, as it checks the tendency to over-luxuriance, which is fatal to the trees fruiting. There is nothing we can see likely to cause the fruit to fall in the treatment of this year; only if the roots are inside, instead of watering once a month, water ought to be given not less frequently than once a week when the trees are stoning and swelling off their crops. With the borders properly drained there is no fear of overwatering Peaches and Nectarines during their growth. The scale can only be destroyed by the applying of an insecticide, than which none is more efficacious than petroleum; a wineglassful to three gallons of water, kept stirred sharply whilst it is being syringed on the trees, so as to keep the oil thoroughly mixed, otherwise it will rise to the surface and be very indifferently applied. Repeat if necessary in the course of a few days, and always in the evening.

Names of Plants (Youth).—3, *Ornithogalum nutans*; 4, *Ranunculus aconitifolius flore pleno*; 6, *Epimedium alpinum*. The other specimens were quite withered. (*H. C. M.*)—1, *Luzula campestris*; 2, Not recognisable; 3, *Carex glauca*; 4, *Carex remota*. (*S. H.*)—*Onoclea sensibilis*. (*W. W.*)—*Pellaea hastata*. (*J. W.*)—The purple flower is *Muscari monstrosum*; the Lily is *Lilium pomponium*; the Iris was much withered, but resembles *I. tuberosa*, the Snake's-head Iris. (*J. V.*)—1, *Ceanothus dentatus*; 2, *Lithospermum prostratum*; 3, *Cistus purpureus*; 4, *Trollius europæus*; 5 and 6, *Lychnis viscaria* and its variety *alba*.

ARABLE AND PASTURE FARMING.

(Continued from page 436.)

It is a natural question to ask, Can the question of comparison as between arable and grass land farming be answered in a way that shall be easily understood by the use of figures? We reply, No; it is impossible. All the attempts which have been made in this direction have proved failures so far as illustrations of profit and loss are considered. If we were to attempt to estimate what quantity of beef and mutton can be made from an acre of arable, or how much from an acre of grass, and also at what cost, it would not forward the matter at all in the eyes of a practical farmer, nor would any estimate (for it could be nothing more) solve the difficult problem, in consequence of surrounding circumstances, which we have never seen precisely analogous on two different farms, although they may be adjoining, and situated in the same district as to climate and soil. The disturbing elements in such a case are so numerous that it is difficult to enumerate, much less to estimate them; but when we come to compare lands occupied either as arable or pasture with the varying temperature of the soils, the rainfall, the geological formation, and the surrounding influences too numerous to mention when situated in different districts, it is totally impossible to solve the problem.

We must therefore for our comparison take farms to illustrate our subject situated on the same estate and in the hands of an agent or home farmer for management. This will simplify the matter very much in consequence of there being no lease with disturbing conditions quite unsuited to the soil and situation, which often ties the hands of the renting farmer, preventing him from making any alteration in the system of cultivation of the arable or the management of a pasture farm. We may probably be able to introduce a variety of methods which different men have found most profitable, and at the same time to allude to certain systems well known, and also to introduce those admitted variations in farming practice which are not only interesting on account of their novelty, but at the same time sufficiently economical to entitle them to a position as profitable farming.

One man recommends as an improvement a new departure in the increased acreage of his cereal products, whereas another falls back upon old-established customs, which may frequently be called old prejudices, by keeping stock of certain kinds, whether of horned stock or sheep, not only ill adapted for the land under his occupation, without ever making any calculation as to the profit or loss on the transaction or system with which it is connected. By so doing he positively destroys all his prospect of profit by diminishing the growth of his cereal and

pulse crops, which being the rent-paying crops, by continuing to maintain and often to increase his live stock, upon which money is frequently lost, without adopting experiments on a small scale in order to find out how those recommended may be suitable and economical as applied to his own occupation. We do not ask any man to blindly accept all that is offered to his notice in farming practices without trying them in his own way on his own occupation.

Before entering upon the comparison of farms of the like character, but managed under different systems, as of grass or arable land, we will quote from Mr. Bowen Jones's summary, to which we have previously referred. He writes:—"My conclusions are that it is desirable for English farmers to turn their attention more to the production of meat. That to do this successfully they must be insured protection from the inroads of foreign diseases which are fatal to this branch of industry. That meat cannot be brought into the market without fostering the breeding of all descriptions of stock in this country. That the condition of soil and climate in some parts of the kingdom will not admit of the whole of the animals bred on the land being there fed. That breeding and feeding on the general run of farms throughout the country should be extended. That on light lands more meat can be raised under an arable than under a grass system of culture; and an extension of sheep-breeding and feeding on such soils will not only increase the yield of meat but the profits of the cultivator. That on strong clays on the average of years less meat can be raised under a system wholly arable than one wholly grass if high feeding is resorted to. That on good medium soils a mixed system of part arable and part grass is the best to raise the largest quantity of meat through breeding and feeding on the same holding. That as you approach the lighter soils the quantity of arable in proportion to grass may be extended for the same purpose and with the same result, and, on the contrary, as you draw nearer the clay from medium soils the amount of grass may be judiciously increased." This is certainly a very fair statement of the results of grazing and corn-growing, and on the assertion that meat being higher in price more stock should be raised. It is, however, only asking that the old system of stocking in connection with cropping upon the old and well-known rotations may be maintained, and, if possible, extended.

Our opinion is that the old system of stocking and cropping having broken down, except that of dairy farming and grazing fat cattle, there must be a new arrangement of both on the mixed soil farms before it can succeed. If we look to any of the best written essays in the Journal of Royal Agricultural Society of England, we find all the best practices set forth in the most practical manner by the most intelligent and experienced farmers, and notwithstanding the failures of a vast number of men who understood both stocking and cropping upon the old lines, it has been recommended to continue it. We shall therefore commence our illustrations of the stocking and management of some of the best grazing farms in England, and endeavour to show what improvement can be made in their stocking and management. Let us take, as illustrative of our object, some of the best grazing farms in the vale of Aylesbury, also in the Wincanton vale of Somersetshire and in parts of Leicestershire, as well as some other counties, on which it is no uncommon practice to feed fat a bullock and a ewe and her lamb also per acre. Upon such land we find it is stated by Sir J. B. Lawes, in an article upon pasture land published in the *Agricultural Gazette* on August 9th, 1880, as follows:—"There is a common saying in Leicestershire, 'The more white Clover the more beef,' and it is evident that in the pasture which I have had under examination where this Clover occupies a very prominent position. It is probable that an increase of live weight equal to 500 lbs. is produced upon each acre of this land in the six-months grazing; but it is hardly possible to form any accurate measure of the amount of grass which is consumed in the production of this result. In our various experiments upon fattening oxen we estimated that about 12 to 13 lbs. of dry food was consumed to produce 1 lb. of increase. Now, without going into the question of how far the grass on an acre of the Leicestershire pasture would be equivalent to the food I have named, its consumption at all events brings about the same result so far as the production of 500 lbs. increase of live weight in a fattening animal is concerned, and we thus get, in the comparison, some idea of the wonderful qualities of such a pasture as that which I have had under examination." This at once shows, in connection with other farms of pasture land which we could mention, the great value of such land, but it by no means shows how many of the best farms may be better conducted. For instance, sheep are kept on the land simultaneously with bullocks, and these we know feed closer than cattle, and eat out the buds and stems of

the white Clover to the injury of the pasture; at the same time the long-woolled sheep are a necessity to feed in company with fattening oxen, for they are of a quiet habit, and will eat and lie down, whereas most of the Down breeds and crosses would continue to roam over the pasture, making the produce distasteful to the bullocks. Again, it is notorious that in much of the best pasture land the inferior grasses have greatly increased, which arises from the fact of its going to seed, it having been refused by the stock; and therefore, unless the scythe or mowing machine is run over the pasture just after these grasses have come into bloom, the seed will drop and vegetate to the injury of the future pasture. Also in all those cases when cake or corn, or indeed in any case, the late Mr. T. C. Carrington always carried out the plan (and he was a great authority on the subject), of spreading the droppings of the cattle twice a week, or otherwise collect the droppings and take them to an earth or compost heap ready to receive them; in this way the full advantage would be obtained by the pasture when spread, because allowing it to remain as usual would make the grass distasteful to cattle if allowed to remain without either spreading, or heaping and laying out again.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour is still connected with preparing the land for seeding and drilling for the Swedish Turnips, and also common Turnips where they may be required for early feeding on strong land preparatory for Wheat, or where they are required for ploughing-in when full of foliage and before bulbing, in which case another crop may be grown and ploughed-in the same way. The seeding for the main crop of Swedes should now be completed, for in all except the northern counties and Scotland, the best time for sowing is between the 8th and 14th of June. The first growth of Mustard will now be ready for ploughing in. This should be done at a depth of about 4 inches, and worked down fine, and the land sown daily as fast as ploughed, in order to insure moisture sufficient for vegetating the seed; otherwise, if the dry weather continues it may lie about in the land, and the weeds become master of the situation. On some strong land, especially where dairy cows are kept, crops for ensilage may be seeded for. After Rye has been taken as a fodder crop, a crop of Maize may be grown, which will come off in good time for use to be placed in silo. If 3 or 3½ bushels of Maize be drilled at 14 inches apart or sown broadcast per acre, with 1½ cwt. of nitrate of soda, it will come very thick and strong, and forward enough to make good ensilage, or for ploughing-in as green manure. As fast as the Trifolium crop is removed for cattle or sheep and horses, the land may be ploughed and sown daily, or as fast as room for ploughing can be obtained, with Greystone Turnip. If required for sheep-feeding they may be allowed to bulb; otherwise when full of foliage before bulbing they may be ploughed-in as green manure for Wheat. In any and every case where Swedes or Turnip seeds are sown or drilled not less than 3 cwt. of bone superphosphate per acre should be applied by the drill. If the weather continues dry at the seed time 1½ cwt. of nitrate of soda may be sown broadcast behind the drill and harrowed in; this will retain more moisture in the land, besides quickening the growth of the young plants out of reach of the Turnip flea or beetle.

Hand Labour.—The cutting of Clovers should not be longer delayed on any soil, for the quality of the hay will be the better for early cutting, as also the second growth, either for feeding or for hay and seeding. Hoeing of Mangolds and all early root crops both by horse and hand should be done early, to kill the weeds in their infancy. Sheep-washing and shearing will now be pretty general, especially on the hill farms where breeding flocks are kept, and the shepherd should always be the party employed to cast the sheep into the water and keep his eye well upon every animal to insure their being taken out in turn, for some good animals are frequently lost or injured by staying in the water too long, especially in those cases of neglect when water is taken internally, for then it is often fatal. Prepare now for making rick staddles for hay, and, unless on some small farms, this is best done to save labour in the fields where the crop is grown. Spars and yarn for thatching should be also provided beforehand. Planting Cabbages and Kohl Rabi will be going on now. In a dry time it is no use planting with the setting stick. We always plant with the spade in any weather; the men introduce a light or worn spade at an angle of 45°, women following to introduce the plants at the back of the spade. In this way, especially if the plants are large, they can be buried deeply in the earth, and are sustained in the driest of weather, whereas if planted with a setting stick the dusty fine earth would run into the orifice with the roots of the plant and cause them to die. Under any circumstances, when very dry and hot weather prevails, the hearts of the plants should be placed just under the surface. Ploughing-in the plants is frequently done, but it cannot be well done in dry weather.

Live Stock.—Calves may in most cases be reared with profit, even without milk, after a few days, with a prospect of advantage in those cases where the stock is short, and where either dairy stock or animals for making baby beef are required. As this is the time for the selection of mares for breeding either cart horses or heavy draught animals, the selection of good mares and using only the best entire horses is of the

highest importance. There is a better guide in selection, by taking the best form on either side, together with their weight as well as age. We find that in America the value of draught horses is judged by their weight, as it is stated that weight gives not only power in work, but is one of the surest indications of constitution; light, flat-sided horses are generally of the worst constitution and are unequal to severe work, and are more frequently short-lived in consequence. With regard to the fattening of steers in boxes in the summer time, the cutting-up and feeding with Clovers, and an allowance of 3 lbs. cake and 1 lb. of bean or maize meal per day, excellent beef can be made, as we have proved for many years, also the feeding dairy cows in the same way for milk in their stalls will furnish a good record, and leave most valuable manure.

THE BRITISH GOAT SOCIETY.—The fifth annual meeting of this Society was held on Friday last at the rooms of the British Dairy Farmers' Association; Mr. W. K. Taunton presiding. Mr. H. S. Holmes-Pegler, Hon. Secretary, read the report, which showed the continued progress of the Society, the number of members being now 225. The funds were likewise in a flourishing condition, the balance-sheet showing the sum of £53 0s. 10d. in hand. The kid register, which was opened on the 1st January for the registration of the birth of goats, was working satisfactorily, and in order to afford a stimulus to registration it had been decided to offer an additional prize, to be given to the breeder of certain first-prize exhibits at the next Dairy Show, conditionally upon the birth having been duly registered. One object of the Society has not met with that success which was anticipated and which the Committee thought it deserved—namely, the introduction of goats amongst the cottage population, very few applications having been received from cottagers for goats to be paid for by instalments. The report was adopted, and some other formal business was transacted. The Duke of Wellington was re-elected President, and it was resolved to ask Mr. James Howard, M.P., to become a Vice-President.

SEED STANDS AT MAIDSTONE.—At the great and successful Show of the Bath and West of England Society, the large seed stands which are the first things to meet the eye of the visitor are, as usual, handsome and well-arranged botanical museums. That of Messrs. Sutton & Sons of Reading is first in order of the catalogue as it is in the show ground, with a handsome black and gold front, and embellished with trophies of victories in all parts of the world. The structure is of a very striking character. Specimens of 300 kinds of Grasses and of a thousand different kinds of seeds would occupy the student for the whole time of the Show if he intended to instruct himself in the subject. Roots and forage plants, models of plants and vegetables, and nearly a hundred samples of Potatoes go to make up the rest of the stand. Messrs. Webb & Sons of Stourbridge come next; and this firm, too, have an enormous museum of Grasses and Clovers, seeds, plants, roots, and vegetables. And not only this, for they also show the manure to help on growth from healthy seed. Messrs. James Carter & Co. of High Holborn have a really handsome and instructive museum. Grasses here are classified into desirable and undesirable sorts, and the geological formation suited for the various kinds pointed out. Seeds and the main features of the other stands are also shown.—(Morning Post.)

WATERING, MULCHING, AND TOP-DRESSING.

CONCERNING the necessity of these operations both under glass and in the open it is needless to speak; but I question if all fully realise their importance in relation to each other, or, in other words, whether watering is not too often solely relied upon. In numerous cases, if there is a necessity for watering there is also a necessity for mulching, and in some instances if the latter were attended to in good time watering might be dispensed with. What is generally termed mulching is giving a liberal surface-dressing of rough manure, litter, or grass, and is intended to prevent too rapid loss of moisture by evaporation from the soil. Top-dressings, as distinguished from mulchings, take the form of decomposed manure, leaf soil, lime rubbish, burnt refuse, or a mixture of these or other fertilising substances with good loamy soil. This, besides to a certain extent acting as a mulching, also serves to attract the roots near the surface.

In all cases, however, some judgment must be exercised with regard to the subsequent waterings, more especially under glass, or, instead of mulchings and top-dressings being of great service, they may become a source of much injury. Much depends upon the nature of the borders and the material used in mulching. One of the greatest mistakes I ever made was to top-dress our Peach borders with fresh straw manure from the cowyard. This border is of a heavy cold nature, and so also is cowyard manure, besides being a very bad heat-conductor. As a consequence, our borders never became thoroughly warmed during the dull summer experienced, and mildew and "yellows" were in the ascendant. Then, again, this kind of manure whenever at all exposed (and if the borders are not exposed there is little necessity for mulching) is very apt to become badly caked over, and in this state greatly interferes with free watering, besides becoming useless as a manure. If the border is rich enough, the roots being near the surface and plenty of liquid manure available, I consider straw litter from the horse stables the best mulching for fruit borders under glass, and this we now rely upon for the Peach borders. For all exposed and partially exhausted borders, both inside and outside, I should recommend that they be given a liberal dressing of short or half-decayed manure, this being covered with a little fresh strawy litter, without which the manure is almost certain to become hard and dry; and in that state, although preventing rapid evaporation, it is not attractive to the roots. If we preserve plenty of roots near the surface fruit-growing is comparatively easy, but the case is very different if either by excessive coldness or dryness a deep-rooting tendency is induced. For my part I am arriving at the conclusion that we attach too much importance to deep culture for vegetables as well as fruit, and I firmly believe nearly everything would thrive better if the manure were well mixed with the surface soil.

Probably the best material for attracting roots to the

surface is leaf soil, and this, if not spoilt, evidently contains more plant food than many of us were at one time aware. This with turfy loam forms an excellent top-dressing for Cucumbers and Melons, being far preferable to manure, which I have repeatedly found breeds insects injurious to the roots, as well as gradually bringing the whole heap to an objectionable close state. All free-rooting plants delight in a loose open soil; in fact, Mr. Challis at Wilton is able to grow better early Grapes on Vines rooting in a border composed exclusively of broken bricks, charcoal, mortar rubbish, and bones than many are able to do in the orthodox close and rich borders. It must be remembered, however, that the more open the border the greater need for frequent liberal supplies of water; also if we top-dress any kind of border, mounds of soil, box or pot plants, we must bear in mind that this will not greatly affect or check the absorption of the moisture by the roots from the soil underneath, and thus we must not mulch dry soil, or the consequence may be distressing. Before a top-dressing is applied care should be taken to loosen the surface of the soil and give a good watering, as if it is placed on a dry hard surface it will not amalgamate, being therefore worse than thrown away. I have seen plants of Tomatoes, Melons, and Cucumbers, and borders for other fruit trees and Vines that have been top-dressed, in some cases filling the new soil with roots, and yet the plants or trees have done badly. This was simply owing to those in charge judging of the plants' requirements by the state of the surface soil, whereas this ought scarcely to be heeded, the amount of water given daily or otherwise being always in such cases in accordance with what was done prior to the top-dressing. If once a small body of soil which is fully occupied with roots is allowed to become thoroughly dry it is a difficult matter to moisten it again, except by dipping; and that is the secret of the failures alluded to, as a moist top-dressing may easily, and often does, cover dry soil. By all means top-dress, but look well to the subsequent watering.

Large inside Vine or other fruit borders, and which we are constantly and rightly informed require frequent heavy waterings, I would mulch only where much exposed to sun or fire heat, preferring rather to occasionally lightly top-dress with decayed manure or leaf soil to which is added some artificial manure, soot, or guano; or, better still, dried night soil as prepared and used so effectively by Mr. Taylor when at Longleat, this admitting of the surface being lightly loosened with a fork and then thoroughly soaked. Rough heavy mulchings interfere with the waterings, and we may easily be deceived as to the amount or thoroughness of the applications.

In the open ground mulchings are of the greatest value, especially for newly planted fruit trees and those growing in raised hot borders. In the case of young trees, which perhaps require no manure, straw litter is sufficient, though we may easily err on the wrong side with them; but well-established Peach, Nectarine, Apricot, Plums, Pears, Cherries, Raspberries, Gooseberries, Currants, and Strawberries will generally be benefited by a mulching of short manure surfaced with straw litter, applied directly after the next soaking rain or heavy watering. Strawberries and Raspberries especially require this treatment, as they ought never to be dug amongst, and must therefore be manured from the surface; the straw, being soon washed by the rains, also serving to keep the Strawberries clean. In town and suburban gardens where the "Companies'" water is laid on, those owning them sometimes over-estimate the value of the supply, and are, I think, rather too lavish with the hose. An almost daily deluge of cold hard water greatly impoverishes the soil and maintains it at much too low a temperature. Better by far run the water into an open cistern to become softened and warmed, and then apply it with the watering can, not forgetting also to mulch freely, and thereby do away with the necessity of so many waterings. If fruit trees, rows of Raspberries, Strawberries, Peas, Beans, and other vegetable

crops, are watered at all they should receive a thorough soaking, as driblets do more harm than good.

It would appear needless to remark that watering is unnecessary during wet weather; but if we wait till the ground becomes very dry, this happening in some cases directly hot weather sets in, the chances are we shall be too late, the ground, especially about gross-feeding plants, having become too dry to be easily moistened again. Supply water, therefore, before the ground is very dry, especially if liquid manure is available, this being best applied during showery weather. This watering should be followed by a mulching of any available rough litter or manure.

Owing to the mildness of the winter and accompanying heavy and frequent rains the ground is become what is expressively termed "unkindly"—that is to say, it does not separate so freely as it does after being well pulverised by the action of frosts, cold drying winds, and rains. We had April weather in March, and that also militated against those especially who, like myself, have to manage cold heavy land. As a consequence the ground binds and cracks badly during hot dry weather, and this must be anticipated both by frequent surface-hoeings and where possible by mulchings.

Manure and litter are not available everywhere; but there are substitutes, such as the grass from the mowing machine and trimmings, while even a little fine dry soil spread over the surface of seed beds after rain will serve to check rapid evaporation and consequent cracking. Flower beds especially are better for being mulched rather than heavily watered almost daily. The soil about the plants should be levelled after a heavy rain has fallen or a good watering given, and a mulching of leaf soil, cocoa-nut fibre, peaty soil, or short grass be given. The beds of Roses also should be mulched, nothing being better for the purpose than manure from the piggeries, this being faced with straw, or, if preferred, covered with a little loose soil. The month of May has been unusually hot and dry, and those who have already mulched different trees and shrubs newly moved, fruit and vegetable crops, may have cause to be thankful for their foresight, and will now reap the greatest amount of benefit from the refreshing rains.—W. IGGULDEN.

CELERY CULTURE.

It is generally admitted that Celery is one of the most important of all our autumn and winter vegetable crops, and to have it in sufficient quantity and in perfection should be the desire of every cultivator. With some it is a difficult crop to grow well, pithy and insect-eaten stems taking the place of sound and clean produce; but in many cases this is the fault of the cultivator, and may generally be rectified at the time of preparing the trenches and in after culture. I have often had soft Celery, but I was never satisfied with it, and now a pithy stick is a rare exception. Different parts of the garden were tried, and it is wonderful how well Celery will sometimes do in one part and how badly in another, especially when the soil varies in character. When, however, unsuitable soil has to be dealt with, the best way is not to run the risk of a failure, but prepare it properly before planting. Of all soils for Celery I prefer a light one, and the quarter occupied with Celery year after year is the lightest part in the garden. Except for exciting root-action, rich soil is not wanted for Celery. Indeed I should be fully satisfied had we only a good bed to plant in, and the surroundings sand or ashes; then insect injuries and loss from damp and decay in winter would be reduced to a minimum. A rich plot of soil might be thought a capital place for Celery by some, but I am only in favour of the poorest, and would never enrich any part of it, excepting in the immediate vicinity of the roots.

This is a seasonable subject, as now is the time to form trenches and plant, and a good mode of dealing with both will be briefly detailed. Trenches are frequently formed of various depths, some being only a few inches, others a foot or more; but the best of Celery may be grown in trenches about 8 inches in depth, and I would prefer having the plants on the level ground rather than in very deep trenches.

No manuring of the land should take place until the trenches have been dug out and formed. To dig manure in all over the surface of the piece and then make the trenches is a waste of manure and labour, but where the soil is heavy it is an excellent plan to spread a thick coating of ashes, sand, lime rubbish, or road scrapings on the

surface, digging and mixing them with the soil deeply. In forming the trenches afterwards the whole of this material will get well incorporated with the soil, and form a composition of the best description for earthing up when the time comes to attend to this operation.

In measuring off the trenches they ought to be cut straight, and the space left between them should always be a little more than their width. I have grown Celery in single rows and up to as many as six rows in a trench, but for convenience I prefer having two rows in each trench. To admit these the trenches should be from 15 inches to 18 inches wide, and the sides should be beaten firmly with the back of the spade, as it is not beneficial for the soil to be sliding down from the sides of the trenches before required for earthing up.

As soon as the trenches have been finished manuring should begin. I would avoid putting a layer of manure 6 inches, 8 inches, or 10 inches in thickness. Cow and horse manures are both good for Celery, and that from earth closets is best of all; but in each case mix them with wood ashes or sand and add 1 bushel of salt or kainit and 2 bushels of soot to each cartload of manure. This should then be put into the trenches in a layer of about 4 inches in depth, and then dig it in deeply. The soil at the bottom of the trenches will not appear very rich, but it will be amply so to produce clean crisp Celery of the best flavour and keeping qualities.

The plants should be lifted with as many roots as possible. By attending well to this very few will flower prematurely, as Celery is so apt to do. They should be let well into the soil, and immediately planting is done, if it does not rain, the bottom of the trench should be thoroughly watered. I do not approve of constant watering, but one or two good waterings given about once a week until the plants have rooted in the soil are sufficient. "Bolting" through dryness at the root is an uncommon occurrence, it more often results from careless planting and transferring the plants to the trenches without any soil to their roots. Then they are a long time in commencing growth, and when they do so it is only to flower and become useless.

As a rule it is a good plan to make two plantations of Celery, one early in June and another about the end of July. The first will be excellent in autumn and until the new year. Then the late plantation will give an ample supply in the spring months. Some of the latter planted last July have not shown signs of seeding yet; it is tough, but does very well for seasoning or stewing. Very early Celery, such as any which may be 1 foot or more in height by this time, will be useful in August and September; but much of it will be useless before the winter comes, and it must not be depended on for that season.

Large quantities of Celery, especially in small gardens, are often ruined through want of being earthed. As a rule it is a bad plan to allow it to grow to the full size and then give one earthing. It takes a long time to blanch in this way, the plants spreading out and falling so much apart that they never become compact afterwards. It is undoubtedly best to begin earthing when the plants are from 10 inches to 1 foot high; then only about 3 inches of soil should be placed round them, and as growth advances the same quantity may be added every three or four weeks until the greater part of the stem has been covered. I may here remark that it is placing the soil against the stems that causes the grubs to begin eating them, and this must be avoided. Rich soil almost always contains insects, hence the objection to it for earthing purposes. With such sand and ashes should be mixed liberally, and at each earthing a quantity of soot and salt should be mixed together, and the soil about the plants, both before and after earthing, freely dusted with it.—J. MUIR.

NOTES ON ORCHIDS.

MR. J. T. PEACOCK'S ORCHIDS.—An exhibition of great beauty and interest is now provided at Sudbury House, Hammersmith, the residence of J. T. Peacock, Esq., who with most commendable liberality has adopted this attractive means of adding to the funds of the West London Hospital. The large and handsome Agave house, which is a lofty span-roofed structure 50 feet high by 18 in width, has been cleared of its usual occupants, and now presents a floral spectacle such as is rarely seen in a private garden. About 1000 Orchids have been most tastefully arranged with Palms, Ferns, and Selaginellas, a centre and two side stages being filled, forming banks of rich and delicately coloured flowers mostly on graceful nodding racemes. There are probably 20,000 flowers expanded, and the effect produced by such a number can readily be imagined. *Odontoglossum vexillarium* predominates, and of this species alone in numerous grand varieties there are over 300 plants, all in the most robust health, and flowering superbly, some having three spikes to a pseudo-bulb. The colours range from pure white to the darkest rose, and there is not a poor variety amongst them all, every flower being not only of great size, but of excellent form also. *Odontoglossum Alexandræ* is

similarly well represented by most carefully selected varieties and well-grown plants, their wax-like exquisite flowers being very abundant. Scarcely less noticeable are some magnificent varieties of *Odontoglossum citrosum* with mauve flowers and fine rosy purple lips, while the lovely mauve-purple flowers of *Lælia majalis* are seen suspended on blocks amongst the others with charming effect. Rich shades of colour are furnished by the *Masdevallias*, such as *Lindeni* and *Harryana*, of which several magnificent varieties are represented. The fine orange-scarlet hues of *Epidendrum vitellinum* enliven the display greatly, whilst scores of panicles of *Oncidium ampliatum majus* supply the brightest shades of yellow. Suspended from brackets at the sides of the house numbers of healthy plants of *Phalænopsis grandiflora* bearing handsome pure white substantial blooms have a most pleasing appearance, their panicles, as in the case of the *Oncidiums* and some of the *Odontoglossums*, gracefully arching over the plants beneath them. The general effect, from whatever point the house is viewed, is admirable in the extreme, and in arrangement all that could be desired.

In addition to the principal features above indicated there are many curiosities and rarities that attract attention on every side. Especially noteworthy is a grand specimen of *Brassia verrucosa* with nineteen spikes, or considerably over 200 of its peculiar yellow and green flowers. Then two plants of *Lycaste Deppei*, each with thirty or forty flowers, are seen, and near them some curious *Masdevallias*, such as *M. macrura*, with yellowish dark-spotted flowers 11 inches across; *M. cucullata*, with its strange dark maroon flowers and light centre, and many others are equally worthy of note. The interesting slipperless *Uropedium Lindeni*, the large yellow *Anguloa Clowesi*, and the dark-streaked *A. Ruckeri* are similarly prominent. Very brilliant also, associated with the Orchids, are the *Phyllocactuses* and *Cereuses*, of which a fine collection is grown at Sudbury House, and many of the plants are now flowering profusely. *Phyllocactus Imperator* and *multiflorus*, the former with superb crimson-scarlet blooms of great size, and the latter with smaller but neat reddish flowers, are effective. *Cereus J. T. Peacock*, which is in the way of *C. M. Hovey*, is also a lovely variety of rich colour.

The exhibition will remain open for ten or twelve days, and no doubt a large number of persons will avail themselves of this opportunity to see one of the finest private collections of Orchids in the vicinity of London.

DENDROBIUM DEVONIANUM.—I send a bloom of *D. Devonianum*, the colour of which I think must have been caused by outdoor treatment last season. I have noticed several of the *Masdevallias*, especially of the *M. ignea* section, much brighter this year than before. The smaller bloom, for comparison, is from a plant which has not been outside with us yet.—G. W. CUMMINS.

[The colour was much deeper than is usual in this species, and there is little doubt that the difference has been occasioned by its stay out of doors. It is probable, however, that it will not prove permanent unless the treatment is repeated.]

VANDA TRICOLOR—ONCIDIUM CRISPUM.—I enclose a flower of *Vanda tricolor*, and I should like your opinion of its merits. It is from a single-stem plant which has borne three spikes, two of seven flowers, and one of six. I also send two samples of *Oncidium crispum*. The smaller one came named *O. crispum spectabile*. I am much pleased with your Orchid notes. I hope they will be continued. They are very interesting and useful for comparison with one's own productions. For instance, someone asked whether plants of twin-flowered *Lycaste Skinneri* were uncommon. I had one at the same time, and desired information on the same point. Then the number of flowers on *Dendrobium nobile* and *D. Wardianum* were given. My best *D. nobile* had twenty-six on one stem of last year's growth, and *D. Wardianum* twenty-four. Such items give an opportunity of judging of our success when we cannot make comparisons by personal inspection.—J. J., Lancashire.

[The *Vanda tricolor* is one of the finest we have seen, both in colour and size. The flower is $2\frac{1}{2}$ inches in diameter, with a clear bright yellow ground and heavy spots, blotches and marbling of red and brown. The *Oncidium crispum* is also a beautiful variety, the flowers being $2\frac{3}{4}$ inches from tip to tip of the petals, and the lip $1\frac{1}{2}$ inch in diameter. We have, however, seen darker-coloured forms. It is much like the variety usually sold as *O. crispum grandiflorum*. The flower named *O. c. spectabile* does not merit its name. It is small, the petals narrow, the brown colour is dull, and the few yellow lines or spots are pale. Far more beautiful is a variety named *marginatum*, which has a border of yellow round the petals and lip.]

ASPASIAS.—There are three or four Orchids in cultivation under the name of *Aspasia*, which, though less beautiful than many of their relatives, are curious and interesting. A good example of these plants is *A. variegata*, shown in fig. 107, which has fragrant green and yellow flowers, somewhat suggestive of the *Miltonias*. Another pretty species is *A. lunata*, of which there is a finer variety named *superba*, with chocolate-barred sepals and petals, and a white lip having a dark central blotch of violet. A yellow-flowered species, *A. lutea*, is also known but it is not very common. They are all inhabitants of South America, and succeed well in the *Cattleya* house.

CATTLEYA MOSSIE.—From a gardener's point of view this old inhabitant of our gardens is still one of the best and most useful *Cattleyas* that can be grown in quantity. When a good quantity of flowers are out at one time they are simply gorgeous, for they possess a great variety of colour, scarcely any two being exactly alike. With a number of plants a long succession of bloom can be obtained which often proves of greater service in gardens than a large quantity at one time. There is no *Cattleya* easier of cultivation or one that will flower with greater freedom on weak small-sized pseudo-bulbs,

Fig. 107.—*Aspasia variegata*.

if only they are produced under the influence of light and air to ripen and solidify the growth. When in flower this variety may safely be used in rooms where gas is not employed, or in the conservatory, where the flowers will last much longer than in the moist atmosphere of the house in which they are grown, provided they are watered with care, protected from cold draughts, or not crowded in the last position amongst other flowering plants. The admission of cold air directly upon the plants is the most detrimental, for they may fail to grow satisfactorily when returned to the heated structure. If the plants remain in the house in which they are grown while in flower remove them to the coolest and driest position. The material upon which they stand and their surroundings should be kept a little drier. Care should also be taken that water does not reach the flowers when syringing, or they will be spotted, and their freshness and beauty consequently spoiled.

CATTLEYA INTERMEDIA.—This variety is not so gorgeous as either the varieties of *C. Trianae* or *C. Mossie*; it is, nevertheless, worthy of a place where these plants are grown. Its flowers are delicate with its rich dark lip and narrow pure white sepals and petals. In some varieties the two latter are lightly shaded with pink, and it is difficult to determine which are the most lovely, the shaded or the white varieties. This *Cattleya* is the more useful because it blooms just after the varieties of *C. Trianae* are going over, and before many of the flowers of *C. Mossie* are expanded; this at least is its character

here grown with those varieties in a winter night temperature of 60°. *C. intermedia* differs from the majority of these plants in not flowering from mature pseudo-bulbs. It commences its growth in early spring and flowers directly the growths are completed. The flowers, which number five or six upon each strong pseudo-bulb, will last in good condition for nearly a month in a cool moderately dry atmosphere. After flowering roots are produced, and in due time another set of growths are made, but from these no flowers are produced. It may be supposed that this *Cattleya* does not need particular attention in ripening or a lengthened season of rest when the flowers are produced upon soft immature pseudo-bulbs. This is not the case, for its autumn growth must be well ripened, and a good season of complete repose is as essential to this as any other *Cattleya*. When making its growth in spring it should have abundance of light and a fair circulation of air to solidify the growth as it is being made, and the results are fine large flowers of good colour and substance. This variety does wonderfully well in comparatively small pots, and will also succeed on a block with a little moss, only more attention is needed in watering, therefore pot culture is preferred. When grown in pots a good per-centage of charcoal used in lumps should be employed amongst the moss and peat used for potting, as the roots like something to which they can cling.

DENDROBIUM PARISHII.—After the majority of spring-flowering Dendrobies are over this comes in most useful, and can be had in good condition over a lengthened period by retarding it in a cool house until later in the season before introducing it into heat. A good plant well flowered is very conspicuous. The pseudo-bulbs should be made under the influence of light, and well ripened, to be followed with a long season of rest. This *Dendrobium* will do well in either a pot or basket; the latter we prefer to grow it in, because its roots have a tendency to get out of the basket into the atmosphere. In which-ever it may be grown it does not require much material to root in, and is much better grown in all sphagnum and crocks than with an admixture of peat. I have several times potted it in a mixture of both, but have never been able to find any roots in the peat, but the roots cling tenaciously to pieces of pot and charcoal. It would be interesting to know if there are two varieties of this Dendrobe, the one with much shorter pseudo-bulbs than the other. I have seen plants with stout stems fully 14 inches in length, while the variety I have only makes them 6 or 7 inches long. The plants in question are not weak, because some of the pseudo-bulbs were sufficiently strong to produce two growths each last year. As well as I can remember there is no perceptible difference in the colour of the flowers, unless in the variety I possess they are a little paler in colour.

DENDROBIUM PULCHELLUM.—This charming miniature-growing variety should have a place in all gardens where Dendrobies are appreciated. It is indeed a gem when covered with its large beautifully fringed *D. Devonianum*-like flowers. It is best grown in a basket with moss and lumps of charcoal, and when once established it should not be disturbed, for it loves to be let alone. When established in a small quantity of rooting material, and the letting-alone principle adopted, it will grow and spread until it becomes one mass all over the basket. I had three or four small pieces given me eight years ago which were planted in a small basket made of hazel; the basket has been decayed several years, and is only held together by the mass of pseudo-bulbs and roots the plant has made. During the whole of this time nothing has been done to the plant except placing a little living sphagnum amongst its roots annually after flowering.

While growing this little Dendrobe requires stove heat, and the moist atmosphere of a genial plant stove suits it admirably. It should be well syringed and abundantly watered until growth is completed. A long rest after its pseudo-bulbs are ripe in a cool house, giving only sufficient water to prevent their shrivelling, is the secret of growing and flowering it well. It is evergreen, and its flowers are not serviceable for cutting unless they are wired, but when in flower the plant is very ornamental and attractive.—W. B. L.

THOUGHTS ON CURRENT TOPICS.

POSSIBLY there was never an article written, however excellent it may have been, that met the entire approval of everybody interested in the subject of it. There were some good articles in the Journal last week, the perusal of which gave rise to a few thoughts that were jotted down in writing. These are placed for what they are worth at the disposal of the Editor, and even at the risk of the thinker getting castigated for his pains.

WORTHY of its position is the article on espalier Apple trees, contributed by a gardener who has evidently proved their worth. By no other method of culture or training can so much fruit be had off the same extent of ground as on the trees in question. But I cannot think it necessary for spurs to be anything like a foot long for bearing grand crops of Apples. If a person cannot

produce all the blossom that is needed for as heavy a crop of fruit as the trees can safely carry on spurs of half that length, he will not win a medal for the successful management of fruit trees. The height of espaliers named, 6 feet 6 inches, is just what espaliers ought to be; and when I see lines of wires 4 feet high I conclude there is a great waste of space, for the foot and a half higher in a length of even 50 yards must give some additional bushels of fruit without the trees occupying any more ground. The transformation of ordinary espaliers into palmette verriers is not a bad notion. Some trees might, no doubt, be benefited by the change; but those on the old style that are well furnished and bearing freely I would leave alone, and so, perhaps would Mr. Luckhurst. I am inclined to think the transformation plan looks just a little better on paper than it would if carried out in the garden, at least by some persons and in the case of some trees; and I cannot clearly see how the space between two trees could be occupied after some feet had been cut from the larger branches and the resulting growths trained vertically. Can your correspondent assist me in thinking this matter out?

VINES come in for a large share of attention. Syringing, stopping, bleeding, and fruit-thinning do not appear to be settled topics. I think, on the matter of thinning, "J. J." is right, and that with very few exceptions indeed the tying-up of the shoulders of bunches of Grapes is a mistake. It makes the bunches look larger it is true, and the crop to appear heavier than it really is. This goes for something in these days of "keeping up appearances" in the vinery; but when the Grapes are off the Vines they are no better looking, if as good, by the spreading-out to which the shoulders have been subjected.

THEN as to syringing during the flowering period. I do not think the viscid exudation on Muscats is easily washed off by a "gentle syringing." The fluid is removed better by a sharp shaking. I think far more Grapes are set without syringing the flowers than by the adoption of that practice; at the same time, as an occasional shower does not impede the setting of Grapes in the open air, an occasional judicious syringing might not be injurious under glass, while the "baking process"—dry roots and a dry atmosphere—is decidedly prejudicial to the setting and swelling of the fruit. It is not everybody, however, who can set Grapes with the aid of the syringe so well as "C., Dorset," appears to do, and I think it very possible that there are both gardeners and amateurs who, if they imitated this method, might be disappointed.

NEXT as to Vines bleeding. Mr. Waiting appears to write rather dogmatically on this matter. "Water is the chief cause of bleeding" is the latest dictum. When Vines are already bleeding copious supplies of water will increase the flow and escape of sap, or water, but how anything done after an occurrence can be the cause of that occurrence I cannot quite see; indeed the matter is beyond my thinking powers entirely, but I may be dull. Let the wood of Vines be ripened completely, also the pruning be done early, and we shall hear little of bleeding Vines even if they are watered freely. If water is the cause of the evil, if it is an evil, it is, I think, the water in immature wood. What think others?

I THINK "Non-Believer" is inclined to be a little hypercritical on the subject of shortening Vine canes. There is nothing practically irreconcilable between the teaching of the late Mr. Pearson and that of "A Kitchen Gardener." Neither of these cultivators would presumably shorten all the rods at an uniform height of 8 or 9 feet in one case, or 12 feet in the other. It is quite as likely that the former gentleman if he were alive would allow some rods to have a bearing length of 12 feet, and that the latter would shorten others to less than 7 or 8 feet. Uniformity in this respect is out of the question. I have seen many rods left 20 feet long for bearing upwards of thirty years ago, but they were not weak; the weak ones were shortened then as now, and I think wisely; and I have seen not a few Vines, especially those newly planted, practically ruined by the canes having been left too long the first season.

My thoughts pass from the prince of fruits to the queen of flowers—Roses. "J. A. B." appears to have been singularly unfortunate with the beautiful and free Reine Marie Henriette. I have had the pleasure of seeing many examples of this Rose, and their condition has led me to think it one of the greatest acquisitions of recent years. I have seen it growing in the same border with Cheshunt Hybrid, growing as strongly and flowering as freely as that valuable Rose, but surpassing it in substance of

petal and colour. Does your correspondent prune his too closely? If he has not already done so let him try it on the "long rod" system, and if he has strong matured wood he may expect plenty of handsome flowers.

ANOTHER queen has been "sat upon"—Her Majesty. What next? Is "J. A. W." a floral communist? I thought when I read the bold letter how suggestive were the initials, and it struck me they were intended to mean what they spell—a bit of—well, good-humoured banter. Even if Her Majesty is large and sometimes flat before fading, like a *Souvenir de Malmaison*, she is a beauty nevertheless before reaching that stage, will find her way into most Rose gardens, and be first in the class for any light variety. Even adverse criticism often does good, and Mr. Bennett will not suffer by the attention that has been directed to this right Royal Rose.

"ADVERSE criticism!" I see the manner of exhibiting flowers is again reached by it. My thought on this subject is that in Carnation-showing no person should be allowed to receive a prize for flowers he did not grow and he did not "dress." Dressing has won many a prize. Comparatively inferior blooms skilfully dressed possess an advantage over better grown examples unskilfully treated; an exhibitor therefore should only have a prize for his own work, not for the work of another person. But as matters now stand it is not only not illegal, but quite permissible, for persons to win prizes at horticultural shows with products other than of their own growing, unless at least there is a rule to the effect that all articles must have been in charge of the exhibitor for a stipulated time for proving his skill as a cultivator. The authoritative exponents of horticulture in this country—the Royal Horticultural Society of England and the Royal Botanic Society of London, abrogated that rule and expunged that condition. It was evaded and cracked and broken, and big shows became of such importance that exhibitors were left free to get examples for staging one amongst another, or any way they could. What is the use, then, of finding fault with a method of exhibiting which is not in contravention of schedules? and what is the use of persons complaining who are suspected of indulging in a practice that is not prohibited? There are, of course, numbers of persons who would rather lose a prize than win it with the aid of another, but all men are not so particular, and complaints will necessarily continue as long as the combination practice exists, whether they do any good or not.

THE method of growing plants in turf as described on page 442 is an excellent one, provided there is no couch grass in the material used, and which it is not desirable to establish in gardens. All ordinary bedding plants will, under favourable conditions, grow better in squares of turf than in pots, and the best evidence has been produced of the suitability of turf receptacles for Vines and Strawberries in preparation for planting; but as I once established some very fine couch in a Strawberry bed and a flower garden—and the plan in that case was certainly not a success—I think it well to mention this circumstance, with the object of giving a hint to others who might otherwise make a similar mistake, and thus introduce one of the most troublesome of weeds into their gardens. I have used clean squares of turf for sowing *Mignonette* in for transplanting.—A THINKER.

THE QUEEN ONION.

WHY does not every gardener cultivate this valuable Onion? I have repeatedly drawn attention to it, and yet again I hear complaints of a broken supply of Onions because the mild winter caused the summer crop to start into growth prematurely in the store shed, and it became worthless before the autumn Onions were ready. Valuable as are the varieties of Tripoli Onions, upon not one of them can we depend for an early supply; but the Queen had good bulbs two months ago, and now there are plenty of really excellent bulbs, many of them being 4 inches in diameter, and are still growing fast. So few of them have run to seed that out of curiosity a row was taken at random, and only five have run to seed out of 135 in it.

The details of culture are few and simple. Sow on or about the 15th of July, not necessarily upon the permanent bed, but thickly upon any spare border. When the plants are 5 or 6 inches high take them up carefully, breaking no roots, and plant with a trowel in rows a foot apart and 6 inches apart in the rows. Water, weed, and keep the soil stirred between the plants with a hoe, and there will be an excellent supply next spring quite ready for use before the stored crop is exhausted.—EDWARD LUCKHURST.

ROSE REINE MARIE HENRIETTE.

A CORRESPONDENT in your last issue says that he has had this Rose for three years and never had a bloom from it. Three years ago a friend—well known to the readers of this Journal—procured for himself and

me a plant each of this Rose in pots. They were duly planted out, and while his, I believe, like that of your correspondent in question, has never produced a single bloom, and is, moreover, now acting as stock to a foster-child, mine produced flower buds the first year to such an extent that sixteen were sacrificed at one disbudding. Last year I had it on a warm wall facing south by south-east, and it was in bloom a fortnight before any other Rose. This year it and the *Gloire de Dijon* came in together. I cannot say much for the quality of the bloom. This year it is coming better, but generally speaking it is a long time in opening its buds; indeed nothing short of a hot day, such as we are not often favoured with, will induce it to open before the petals have lost the rich red colour shown in the bud, and have become of a washed-out pinky hue. The foliage, too, which is very fine, is tender, and is rendered unsightly by cold winds, which do not affect Teas growing on the same wall.

To an amateur who has but little space, or who has to look at both sides of a shilling before spending it, I would say, Wait a bit; the Rose may prove valuable, but at present there are more enticing investments in the market.

One word more. This Rose will strike in the open like twitch, scarcely a cutting failing. I see it will also bloom when on its own roots, but more I cannot at present say.—W. R. BLAND, *Derby*.

BOG GARDENS.

VERY few gardens of any pretension are without a swamp or bog garden, natural or artificial, and which with a little judicious care and management in selection might be made most attractive, and where now we may only find in great abundance Nettles, Rushes, and many other coarse-growing plants. That much may be done to enliven such places is fully proved in not a few gardens at the present time in various parts of the country. The choice of the plants most suitable for the different situations and aspects should be considered, and at the same time with regard to their seasons of flowering. In making artificial bogs shady corners should be chosen, and might be made to teem with interest.

In the country few gentlemen's gardens are without a natural stream or swamp, and these, with very little trouble might, and ought to be, made as beautiful as many of our mixed borders. In such places we may find the beautiful *Spiraea palmata*, and its varieties *intermedia* and *alba*, quite at home, adding a charm rarely felt in such situations, and enlivening the landscape. Here also may be introduced, with a sure hope of success, all the stronger-growing and charming-coloured *Iris Kämpferi*, a damp situation to all appearance being the main requirement for their successful cultivation. The *Typhas*, too, although many are natives of our own country, seldom get the attention which they deserve, for when planted with a view to natural effect they give a quiet at-home rest to the eye at times, and where glaring colours would be discordant. The great Spearwort (*Ranunculus Lingua*), with its large, handsome, sulphury-yellow flowers, and pretty glaucous stem-clasping leaves, would also be quite at home here, along with the Bog Bean (*Menyanthes trifoliata*), in the more swampy places, the flowers of which are prettily fringed, and almost, if not quite, equal to an Orchid in chasteness of design. The Spike Rush (*Eleocharis*), and the Cotton Grasses (*Eriophorum*), with their white woolly heads, lend to the scene a naturalness which it would be hard to imitate or arrange with an entirely artificial and exotic flora. Then amongst foliage plants many of the *Acanthads* might be introduced into the drier places with advantage, as also *Cladium mariscus*, *Saxifraga peltata*, *Equisetum maximum*, *Carex pendula*, *Rogersia podophylla*, and many others. A place might also be found for the Marsh Shield Fern (*Nephrodium thelypteris*), and also for Her Majesty, the Royal Fern (*Osmunda regalis*).

Among dwarf-growing plants we have also a large collection from which to choose, and as much must be left to the taste or inclination of the cultivator, mention of a few of the best and most suitable may suffice. On damp, but slightly raised positions, the charming Bog Pimpernel will find a home; and here special care must be given to keep weeds, mosses, &c., at a distance, as it might easily be overlooked, so close does it cling to the soil, forming as it creeps along a complete carpet, which in June is studded with its pretty pink blossoms "quite a picture." *Mentha Pulegium* is also suitable for such places, *Sibthorpia europæa*, *Samolus Valerandi*, and many others with the same low creeping habits.—D.

SYRINGING VINES.

THE excellent remarks on this subject by "C. Dorset," favour my previous observations rather than otherwise, as he states that much care is needed to avoid the injury that would surely follow. This being so where first-class appliances are used shows the syringe to be a dangerous tool at the period I remarked when used by amateurs like myself working under difficulties, with old houses badly ventilated, and very little coal.

I tried it once before thinning, but will never do so again. "C., Dorset," gives me and others much information on this subject—information which is not usually given unless elicited by amateurs like myself, learning and working under difficulties, giving their experience and results freely. First-class gardeners often have failures and are at fault, but they do not generally own them or publish them. I wrote from experience and results. I think the slender stalks of the Grapes are often injured by the use of the syringe at the time I named, and especially when recently thinned, and there is not much heat at command.

My remarks had more reference to the use of Hudson's dry soap at that particular time than in condemning the syringe when used with due care at proper times. Where there is little or no heat at command I would never syringe after the Grapes were thinned, but plenty of water must be thrown on the floor. Scalding results more from water hanging on them a long time than from real heat or other cause.—J. E. WAITING, *Grange-over-Sands*.

INSECT PROSPECTS OF 1884.

WE have had an April and May exceptionally dry. One very obvious and natural result is the swarms of the aphid tribes, which have greatly infested many plants lately, especially those of the Rosaceous order, both wild and cultivated. These insects do not like the heavy rains that we sometimes have during spring, by which they are washed off their food-plants, and seldom regain their footing; but a low temperature with easterly wind does not hurt them at all—nay, appears rather salutary to them. It has been noticed that weather which favours them does not so well suit their insect enemies, hence is an additional cause of their rapid increase. Another insect common at this season, and of rather disgusting habit (*Cercopis spumaria*), the Cuckoo-spit, if not more prolific than usual, has proved particularly hurtful to plants suffering already from the unseasonable weather, for the dryness of air has led the species to take deep draughts of the sap, which the plants could ill afford to lose. Centipedes and millipedes have been reported abundant in various localities, and it is stated the wireworms (larvæ of *Elatér* sp.) are benefited by a moist winter, as they can continue to feed, while frosts drive them deeper into the earth and render them torpid.

There is, however, another side more favourable; the mild and wet winter has rendered it easy for many quadrupeds and birds that feed partly or entirely upon insects to remove them from their winter retreats, underground or in the stems or roots of plants. Then the dryness of the land during the past spring has probably checked the emergence of some moths and other insects which had been in the pupa state since the autumn; also, amongst the early broods of caterpillars, hatching out of the eggs laid late in autumn or in the spring of this year, there has been much destruction of life, consequent upon the very ungenial nights and the fierce winds that have been so prevalent.—ENTOMOLOGIST.

CEREUS MACDONALDIÆ.

THE finest Cactus bloom I have ever seen was at Cromwell House on Tuesday evening, May 3rd. Part of the arch on which it is grown may be seen in fig. 93 of your issue of May 22nd, and is formed of galvanised wire netting stuffed with moss, in which the several varieties of *Cereus* root freely. It opened after sunset, and when the house was illuminated with electric light the scene was beyond description. The great specimens of *C. peruvianus* and various shades of colour in flower on smaller plants below gave the whole such an appearance as is seldom seen in an English garden. The bloom when fully expanded measured 14 inches across, and when closed in the morning was 17 inches from the stem to the top of the petals. Mr. Wright crossed it with the pollen of *C. speciosissimus*. Mr. Major may well be proud of his collection with such gems as the above, and I am sure every grower of Cactæ must feel greatly indebted to Mr. Castle for his very interesting and instructive articles on Cactaceous plants.—G. W. CUMMINS.

SMALL POTS FOR AURICULAS—WOOLLY APHIS.

WILL you allow me to add a few words to the remarks you kindly inserted last week on two points that I find I had omitted? The former of these will be opportune to amateurs intending to try Auriculas.

I would suggest that until better advised they use small pots. I nowhere see any good, but much the other way, resulting from the use of pots beyond 4 inches in diameter for the largest plants, and after a comparative trial some varieties, especially the more inconstant, as *Lycurgus*, *Mary Ann*, *Smiling Beauty*, will be placed in the 3½-inch pots I most prefer. I have over and over again observed the plants bloom indifferently where 5 and 6-inch pots are used, and all the best collections I know are restricted to the smaller sizes named.

Last month I saw the sole case of woolly aphis, which came under my notice, although I was told of another near. It had been imported from the south, and before it was detected the roots of nearly all the plants were infested with it, but by washing and planting them in frames the pest had been greatly reduced. I declined with thanks the suggestion to "take a breed and try." I did not like its appearance, and shall continue by washing with fir-tree oil all arrivals from proclaimed or suspected districts, and the enforcement of strict quarantine, to prevent its obtaining any footing with me.

May I add that, passing over the slight misprint in my last notes (page 446) in reference to the way "one gets on" in getting hold of

the rarer varieties, the substitution of "plantation" for "plantain" somewhat increased the extent of the odds against the Auricula.—A NORTHERN AMATEUR.

CYRTANTHUS MACKENII.

SEVERAL very beautiful and brilliantly coloured species of *Cyrtanthus* are known; but though the one shown in fig. 108 does not excel in brightness of colouring it is one of the most graceful and free-flowering of the genus. The flowers are creamy white, or occasionally with a distinct yellow tint, and they are produced on strong scapes 6 to 9 inches in height. It is

Fig. 108.—*Cyrtanthus Mackenii*.

very easy of cultivation, succeeding well in an ordinary greenhouse, but it requires a moderately rich light soil, and plenty of water when growing. I have had it for several seasons extremely fine in 60 and 48-size pots, and strongly recommend it for more extended cultivation.—L.

CERTIFICATED PLANTS.

THE following plants were honoured with certificates at the recent Show of the Royal Botanic Society at Regent's Park.

To Messrs. J. Laing & Co., Forest Hill, for
Tuberous Begonias, *General Gordon*.—Double, bright scarlet, very full and well formed.

Distinction.—Single, soft clear rose with a white centre; petals very round, and general form of the flower admirable. One of the most handsome varieties yet obtained, and certainly one which will become a great favourite.

Earl of Chesterfield.—Single, a magnificent flower 4½ inches in diameter, rich bright scarlet; most imposing.

Lady Chesterfield.—Single, of a bright pleasing rose colour; flower

of great size, about 5 inches in diameter, the petals being 3 inches across, rounded and symmetrical.

T. Hewitt.—Double, very full dense flower, dark scarlet.

Mr. H. Forbes.—Single, scarlet; a large, bold, handsome flower, well proportioned.

Mrs. Weekes.—Single, white margined with rose, petals round; an exceedingly pretty and distinct type.

Her Majesty.—Single, blush white, very delicate tint; the flowers 4 inches in diameter, round and symmetrical.

Caladium Madame Mitzand.—Leaves large, bronzy red, with bright red veins.

Caladium Baron James de Rothschild.—A pretty variety; leaves white with dark rose-coloured veins.

Caladium L'Aurore.—Leaves suffused with rose, having darker-coloured veins and a creamy edge.

Gloxinia Mrs. Coomber.—A distinct and handsome variety with large well-formed flowers, rich rosy crimson spotted on the lobes and margined with white.

Gloxinia Beauty.—Dark purple with a white margin, broad and well defined, dotted with purple; peculiar and pretty.

Gloxinia George Amer.—Rich rose with a white margin, finely dotted with rose. An exceedingly pretty variety.

To Messrs. W. Paul & Son, Waltham Cross, for

Rose Etendard Jeanne d'Arc.—A Tea variety with globular creamy white flowers, extremely fragrant; free and of good habit.

To Mr. H. James, Castle Nursery, Lower Norwood, for

Odontoglossum polyxanthum.—A handsome Orchid; the sepals and petals yellow barred with rich brown, the lip broad and fringed.

Odontoglossum mulus.—Very pretty; ground colour yellow with numerous bars and blotches of brown, the sepals, petals, and lip being tipped with yellow.

To Mr. Cypher, Cheltenham, for

Cypripedium Ræbelinii.—A new species in the way of *C. lævigatum*; the sepals white striped with dark purple; the petals narrow, twisted, 5 inches long, and of a purplish tint.

To Mr. B. S. Williams, Upper Holloway, for

Cypripedium ciliolare.—A handsome species suggestive of *C. superbiens*, of a purple hue, with regularly striped dorsal sepals and spotted petals.

To Messrs. R. P. Ker & Son, Liverpool, for

Croton Flambeau.—Very elegant; leaves narrow, 1 inch wide, 12 to 18 inches long, red, dark green and yellow, prettily mottled.

Croton Sunrise.—One of the most distinct and best-coloured varieties yet obtained; leaves 1½ inch broad, 12 to 18 inches long, bright golden yellow mottled with red and green.

Croton mosaicus.—Bolder in habit than the preceding; leaves 2 inches broad, 12 to 14 inches long, deep crimson mottled with dark green and yellow. Very handsome and effective.

Ficus elastica variegata.—Previously described on several occasions. A useful plant, preserving its variegation well.

To Messrs. Sander & Co., St. Albans, for

Odontoglossum elegans superbissimum.—A charming variety; ground colour, creamy white, with narrow sepals and petals, dark brown bars and blotches, and a yellow base to the lip.

To the New Plant and Bulb Company, Colechester, for

Acer palmatum roseum.—Similar in form to *A. palmatum aureum*, which has been previously described, but of a uniform bright red colour.

To Mr. H. Little, Hillingdon Place, Uxbridge, for

Pelargonium G. Shepherd.—One of the decorative varieties; the flowers of good size, scarlet edged with white; very showy and free.

Pelargonium Harvester.—One of the same type, with crimson lower petals, dark maroon upper petals, and a light centre; good habit.

VINES BLEEDING.

I HAVE read my notes on the above subject, and fail to see what cause I have given Mr. Waiting to speak of "beliefs, doubts, statements, and incredulity." Any candid reader will see that the statements unsupported by facts are on his side, not mine. I ask for proof, he has given assertion. He has also changed ground. In his former notes he said that water was "the" cause of Vines bleeding—now he says it is the "chief" cause. Why this change? If he was right in the first instance, why not hold his ground? and since he has conceded this much how are we to know where his concessions will end?

But he does not even attempt to answer my question as to why in a house one or more Vines should bleed, they having the same treatment with those that do not. Neither has he attempted to make good his assertion that bleeding is a great injury to Vines, and until he does this it is unnecessary for me to write more on this subject.

I see no reason why my belief or incredulity should puzzle Mr. Waiting, but perhaps it is what he is pleased to term my threat of a visit that is the real puzzle.

So far as I am able to judge, there is nothing surprising in the fact that a Black Hamburg cane 11 feet long should produce twenty bunches of the weight named; but to anyone who has seen Black Hamburg grown year after year there is something astonishing in the assertion that eleven and nine bunches respectively, weighing about three-quarters of a pound, should even form a perfect chain from the roof to the floor of a house 11 feet high. With his averages I have nothing to do. I await proof of his assertions.—JUSTITIA.

I AM not surprised that your correspondent Mr. Waiting's statements have attracted attention, because, like his Vines, they "will not hold water," notwithstanding the confident tone in which they are put forward. Mark his declaration at page 345 that "He could and would have stopped the bleeding of his Vines, but, accepting the theory of several writers that the so-called sap was only water without substance, he let them continue until they ceased." A likely plea this! Did ever anybody before hear of an intelligent gardener suffering his Vines to bleed to death, for anything he knew, on the strength of statements in a doubtful controversy, with the power of prevention in his own hands if he chose to use it, and therefore save all risk? I deserved to lose my crop, as Mr. Waiting has done since, if I acted in the same way and let bleeding go on when I could have turned the tap off, so to speak, and stayed it.

I have a conviction, however, that the real reason Mr. Waiting did not stop his Vines from bleeding was because he could not stop them if he had tried when once they had begun, neither by his plan of withholding water nor any other, save by lowering the temperature to as near the freezing point as possible (a thing seldom practicable) to arrest circulation, and painting the wounds after when dry with styptic. Having propounded the water theory it did not, however, suit your correspondent, I suppose, to admit that he could not prevent the bleeding. Blaming your contributors for the consequences of his own neglect will deceive no gardener. Mr. Waiting does not seem to encourage the proposed visit of "Justitia," and I am not surprised at it.

As to water being the cause of bleeding, your correspondent is safe in that view thus far—that a Vine without any water (sap) in its tissues could not bleed—if he ever saw such a phenomenal Vine; but water is not the "cause" which is wounding the Vine not long before the sap begins to rise. If water was the cause most Vines in the country would have bled to death by this time.—NON-BELIEVER.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Major F. Mason in the chair, the following candidates were unanimously elected Fellows—viz., John Ashton, Richard Bannister, Stanley Dent, Thomas Young.

— AT the Committee of the NATIONAL ROSE SOCIETY on Tuesday, the Secretary, the Rev. H. H. D'Ombra, exhibited a box of three Roses, consisting of two magnificent blooms of David Pradel, grown by Mr. Eckroyd Claxton of Liverpool, and a fine bloom of Etoile de Lyon, grown by Mr. Hall of Larkwood, Rockferry, which was greatly admired, and for which a vote of thanks was given to the gentleman who had so kindly sent them.

— MR. J. UDALE, The Gardens, Shirecliffe Hall, Sheffield, sends us an excellent sketch of a DOUBLE-SPATHED RICHARDIA, in which there are two spathes of full size and ordinary form opposite to each other, but one slightly the larger partly surrounds the base of the other. We have seen similar examples to this before, but they are not common, and whether the double form is more ornamental than the other is simply a matter of taste.

— THERE appears to be considerable difference in the extent of the GOOSEBERRY CROP in various districts, and even in neighbouring gardens; but it is extremely probable that the mode of pruning has something to do with this variation. We recently saw two gardens in Kent; in one the bushes were loaded with fruits, and in the other there were very few, but the plants had been very differently treated. In the former the pruning had been confined to removing a few superfluous branches and shortening some that were excessively long, whereas in the other the bushes had been pruned hard for several seasons. Similar examples may be seen in the neighbourhood of the metropolis, and in nearly every case the unpruned bushes have the best crop of fruit.

— INQUIRIES are frequent for TREES SUITABLE FOR SEASIDE GARDENS, and it is usually difficult to find sorts that will thrive in such positions. On the west coast of England, and especially in Lancashire, where the south-west gales are so frequent and violent, the difficulty is still further increased. In several towns there, but particularly at Southport, Sycamores are largely planted as screens and to form avenues in the principal streets; but as an ornamental tree none surpasses *Ulmus montana pendula*, which appears to luxuriate in the sea breeze, provided the position is not too exposed. Many beautiful specimens of this hand-

some tree are noticeable in the Southport Gardens, and their condition is most satisfactory.

— THE WESTON-SUPER-MARE AND EAST SOMERSET HORTICULTURAL SOCIETY will hold their annual Exhibition on August 19th.

— THE "COUNTRY GENTLEMAN'S REFERENCE CATALOGUE" (Barnicott & Son, 44, Fore Street, Taunton) is a useful list of works upon gardening, agriculture, and various branches of natural history, with brief descriptions and prices. A copy just to hand contains 126 pages, with a full index.

— "R. P. B." sends us a box of SPRING FLOWERS, fresh and beautiful, comprising the following:—*Clematis montana*, a perfect wreath of beautiful white flowers; *Anthericum liliastrum*, with grass-like foliage and white flowers; *Spiraea Van Houttei*, bearing abundant small trusses of neat round white flowers on red peduncles; *Ourisia coccinea*, very bright, the flowers rich scarlet tubes on long stems, and with heart-shaped leaves; *Iris graminea*, a charming plant, with long grass-like leaves and purple-blue flowers, prettily veined; *Meconopsis cambrica*, a striking plant, with bright yellow Poppy-like flowers and divided leaves; and the rich blue-purple *Myosotis Imperatrice Elizabeth*.

— THE ROYAL BOTANIC SOCIETY'S EVENING FETE is announced to be held in the Gardens of the Regent's Park on Wednesday, July 2nd, when the usual exhibition of floral decorations will be provided. The schedule enumerates fourteen classes open to all exhibitors, three prizes being offered in each, value from £10 to 10s. The principal class is that for floral decorations for a room, the prizes being £10, £7, and £3. Classes are also devoted to dinner-table decorations, one for hardy flowers only, and a third for three groups of hardy flowers for the table, one kind of flower only in each. Others are provided for baskets, bouquets, &c., and one for flowers which only expand at night.

— A PLEASANT GARDEN PARTY.—A correspondent, "H.," writes:—"Miss Jekyll of Munstead near Godalming, Surrey, kindly invited upwards of fifty gardeners from the principal gentlemen's seats in the surrounding neighbourhood of Godalming and Guildford on Saturday afternoon last, June 7th, to see her choice and very extensive collection of hardy flowers. Previous to being shown round the gardens they all sat down to tea, so liberally provided by this kind patroness of the craft. The gardens were in most excellent order, and were very much admired. Great cultural skill and artistic taste in arrangement are manifest throughout the whole place, which does great credit to Miss Jekyll and all concerned. All the visitors expressed themselves highly delighted with the entertainment, which seems to be a step in the right direction."

— WE have received the schedule of the LEEDS FLORAL AND HORTICULTURAL EXHIBITION, which opens on the 25th inst., prizes which ought to be sufficient to secure a fine display being provided throughout the seventy-five classes. In the chief classes—namely, for twelve stove and greenhouse plants, and for a group of plants for effect, the amounts are in the former case £12, £8, and £4; and in the latter £10 (given by the Mayor of Leeds), £6, and £3. The schedule states that "The prize list has been augmented by £50, which is considerably more than the profit upon the Show last year, and if the public support the Company in the undertaking, they will be enabled to extend the prize money still further, and thus make the Leeds Show what it ought to be, second to none in the kingdom." The railway companies convey plants free from the Show when they remain the property of the exhibitor, and the prize money is to be paid on July 3rd. Mr. G. Bush is the Secretary.

— A "REPORT OF OBSERVATIONS OF INJURIOUS INSECTS AND COMMON CROP PESTS IN 1883," by Miss Eleanor A. Ormerod, has recently been issued (London: Simpkin, Marshall & Co.), and, like preceding issues of the same work, it contains a considerable amount of interesting and useful matter. Chapters are devoted to the insects infesting the Apple, Bean, Cabbage, Turnip, Carrot, Celery, Cherry, Corn and grass, Gooseberry, Hop, Mangold, Onion, Parsnip, Pear, Peas, Pine, Poplar, Raspberry, and Strawberry. These are illustrated by figures of the principal enemies in various stages of growth, and a long appendix is devoted to a consideration of the Hop aphid.

— HUDDERSFIELD CHRYSANTHEMUM SOCIETY.—We are informed that a Committee of forty members has been formed for promoting a Chrysanthemum Show at Huddersfield, and in consequence of the

financial support accorded it has been resolved to hold the first Show of the Society on November 14th and 15th. A schedule is in preparation and will be shortly issued. Mr. John Bell, Royal Hotel, Huddersfield, is the Honorary Secretary.

— "M. S." writes that "one of the prettiest of dwarf plants now in flower on the Kew rockery is the handsome *HEUCHERA MICRANTHA*, which has been freely distributed lately under the title of *H. erubescens*, probably a misrendering of *H. rubescens*, but which is a totally different but allied plant. *H. micrantha* grows from 1 to 2 feet in height, and the leaves are few, round-cordate or oval-cordate, and about 3 inches in diameter, the lobes blunt and deeply toothed, and having hairs on their veins or ribs. The flowers are produced in loose panicles and are very graceful, with quite a unique appearance. It is found in woods on the coast ranges of Sierra Nevada, and may be cultivated easily in a shady nook in the rockery, using a good admixture of peat and leaf soil with the loam."

— THE fortieth Exhibition of the DISS HORTICULTURAL SOCIETY will be held at The Lawn, Diss, on Tuesday, July 8th. Ten classes are devoted to Roses, and in addition a challenge cup value £10 is offered by Francis Taylor, Esq., for the exhibitor who gains the first prize for thirty-six blooms twice. This prize was first competed for in 1883, and won by the Rev. H. E. Berners, Harkstead Rectory, Ipswich. Classes are provided for decorations, plants, vegetables, and fruit, and twenty-two classes are reserved for cottagers.

— MESSRS. T. CHRISTY & CO., 155, Fenchurch Street, London, E.C., write as follows respecting PEPPERMINT OIL:—"We wish to direct your attention to the profit attached to the growing of Japan Mint, owing to the largely increased demand for menthol, or the crystals extracted from the oil expressed from the Japan variety of Peppermint (*Mentha arvensis piperascens*). The subjoined extract from the *Public Ledger* of June 3rd is very important:—"An American correspondent informs us that the constantly and rapidly increasing demand for menthol, of which the supply is so greatly diminishing at a most inopportune moment, is having a strengthening effect on the market for peppermint oil of all descriptions; as in the manufacture about 60 per cent. of this oil is consumed; the demand at present existing for this particular use is quite expected to consume about 70 per cent. of the present stocks, and as it is now ascertained that the planting of the herb is small, it is not at all likely that the entire new crop will be sufficient to supply the requirements of this demand alone. The production of the last three or four years has been nothing like equal to the consumption, and the present world's stock of peppermint oil is, without question, not one-twentieth of what it was a few years ago, when prices were only some 10 to 15 per cent. below what they are now: the last time when the position of the article was as it is at present, values were nearly double what they are now quoted. The demand here is strong at three dollars nett per lb. for oil in bulk." This plant is perfectly hardy, and of as easy growth as our own Mint. Menthol crystals, that two and three years back we bought at 6s. and 8s. per lb., are now 40s. and 45s. per lb."

— THE Rev. D. Landsborough has recently paid a visit to a coal mine near Kilmarnock, Ayrshire, and thus describes the FOSSIL FERN BEDS:—"The fossils are here in considerable abundance and variety, but those who imagine they are to be had without labour are much mistaken, as they are embedded in the solid rock, from which they are with difficulty extracted, and are very frequently broken or otherwise injured in the process. We saw no specimens of *Stigmariæ*, *Sigillariæ*, or *Lepidodendra*. The fossils consisted almost entirely of Fern stems and fronds. The most common was *Sphenopteris latifolia*, bearing a general resemblance to a *Lastrea*. There were also specimens of *Neuropteris gigantea*, *N. Joshii*, *Odontopteris (lingulata?)*, *Pecopteris (muricata?)*, &c. A large specimen of any of these Ferns is valuable, as more knowledge of the plant is obtained from the examination of one such specimen than from many broken pieces. This is owing to the different appearance frequently presented by different parts of the same plant. Mr. Graham, the oversman, had by this time joined us. He has two specimens which quite puzzle me, and which I must refer to higher authorities. These Ferns, now lying under a weight of 700 feet of solid rock, before this rock was formed, grew on what was then the surface, enjoying the light of heaven. A pool of water was here connected with a stream. These Ferns were brought down by the stream, carried by an eddy into a quiet corner of the pool, where they were deposited, just as I have a hundred times seen *Algæ* spread out, as these Ferns are, in all

their beauty in sandy pools at Saltcoats. When thus outspread they have been gently covered by a fine light-coloured clay, have gradually been carbonised while the clay has been converted into rock, and now at the end of ages they have been visited by a resurrection morn. The beauty of the plants is much heightened by the dark colour of the carbon contrasting with the light-coloured stone in which they are outspread."

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY to be held at 25, Great George Street, Westminster, on Wednesday the 18th inst., at 7 P.M., the following papers will be read:—"The Equinoctial Gales: Do They Occur in the British Isles?" by Robert H. Scott, M.A., F.R.S., President. "On the Physical Significance of Concave and Convex Barographic and Thermographic Traces," by the Hon. Ralph Abercromby, F.R.Met.Soc. "Maritime Losses and Casualties for 1883, Considered in Connection with the Weather," by Charles Harding, F.R.Met.Soc. "The Helm Wind," by the Rev. Joseph Brunskill, F.R.Met.Soc. "Climate of the Delta of Egypt in 1798-1802 during the French and British Campaigns," by W. T. Black, F.R.Met.Soc., Surgeon-Major. The Commemoration Dinner will take place at the Holborn Restaurant, High Holborn, on Tuesday, June 17th, at 6.30 P.M.

— AWARDS AT THE BATH AND WEST OF ENGLAND SHOW AT MAIDSTONE:—Fruit cup, Mr. C. Haycock, gardener to Roger Leigh, Esq., Barham Court, Teston, who staged fine Melons, Peaches, &c., and plates of well-kept Apples—Alfriston, Ostogate, Belle Bonnier, and Calville Rouge. Second, Mr. Waterman, The Gardens, Preston Hall. In vegetables they were reversed, Mr. Waterman being first with a fine named assortment in clean and fresh condition. Mr. C. Haycock second. The cup for Orchids fell to W. E. Brymer, Esq., M.P., of Dorchester (Mr. Poyle gardener); Mr. Cooke being a good second with a fine group from D. Barri Crawshay, Esq., Rosefield, Sevenoaks. The cup for the best specimen Orchid fell to Mr. C. Haycock, who staged a well-grown *Vanda suavis*. A good collection of vegetables also came from Mr. Wilson, gardener to G. Ashley Dodd, Esq., Surrenden Park, Ashford. Melons, Strawberries, and Cayenne Pines came from Mr. McKenzie, Linton Park Gardens.

— GLASS STRUCTURES AT MAIDSTONE.—At the Show above named, although the glass erections were not numerous, they presented a few features worthy of notice. Messrs. Wright & Co. showed some pits and lean-to houses; Messrs. W. E. Rendle & Co. houses showing their patent system of glazing. Mr. W. Richardson, Darlington, showed a wall-tree protector and lean-to vinery, and a very handsome small conservatory in the Queen Anne style with admirable ventilating gear. Mr. W. Parham, Bath, also showed some useful houses. Messrs. Foster and Pearson of Nottingham showed their prize-medal pits, the ventilating gear of which is still further improved, and also a very well made and proportioned small greenhouse; a new latch of solid brass is at once a marvel of utility and usefulness, being not liable to get out of order. Mr. A. T. Goodwin of Maidstone showed a novel plant house; the glazing being done in sashes allows the putty to harden well before being exposed, and a house can be put up in a few days. The ventilation was also good, one side of the ridge being opened at a time to avoid draughts. The inconvenience of brickwork and the consequent litter and trouble is avoided by using a foundation of concrete blocks, which any labourer can lay. They give the house a neat appearance, and the house generally would be suitable for the villa garden. In looking over these houses we were struck with their low price, machine-work and the present price of glass bringing them within the reach of persons of moderate means. Messrs. Foster & Pearson sent a model of their "Chilwell" boiler, which appears admirably adapted for heating a large extent of piping.

PLANTING AND ARRANGING FLOWER AND SHRUB BEDS.

THERE seems to be a difference of opinion as to which is the most suitable mode of planting flower and shrub beds. Generally the planting is commenced in the centre. This may seem the best system to some people, but gardeners, who have had to arrange flower beds so that they may have a uniform appearance when finished, have come to the conclusion that they must not commence planting in the centre. I daresay there are many readers of the Journal who have commenced planting in the centre of a bed, and when they came to the last row outside have found that the plants will not fit in well, and the result generally is that many of the plants have to be re-arranged. If the planting commenced at the outside this irregularity would not occur, and in finishing the centre is easily filled. It is the same when planting a bed of *Rhododendrons* or other shrubs. If the outside rows are planted first the centre plants can be arranged so as to have an artistic and workmanlike finish. If there is likely to be any difficulty in carrying the shrubs into the bed

after the outside rows are planted, and if the plants are of large size, two or three may be left out of the outside rows, when the centre plants may be easily carried in. But in planting flower beds fill up as the work proceeds; the soil or plants will not be trampled if the workman is careful. Another advantage of this system of planting is, if the supply of plants is short they can be widened out and would still look well. There may be exceptions to finishing in the centre. In round beds, for instance, there may be a specimen plant to be placed in the centre; this should be planted first; but still commence at the outside when planting the groundwork of the bed.—A. YOUNG.

RODGERSIA PODOPHYLLA.

THIS is a rare herbaceous plant, and one eminently fitted for cultivation by the side of lakes and small ornamental waterways, its large, graceful, and attractive foliage being very conspicuous in the distance where the plant is grown in quantity. The leaves are divided into four nearly equal diamond-shaped leaflets, of a very agreeable light green colour, which makes a fine contrast with the brown or purple finely serrated edges. The flowers, although individually small, are numerous produced on long clustered spikes rising well above the foliage, whitish, and not unlike our common Meadow Sweet in general appearance. To grow it well it requires strong rich loam, and will be all the better for occasional feeding during the growing season. It should be planted close to the edge, and will be all the better for having its roots touching the water. The beauty of this plant under the above conditions will amply repay any small attention it may require during establishment.

The Peltate Saxifrage (*S. peltata*) will be found to be a very suitable companion to the above in every way; indeed they may be very advantageously grown side by side, their appearance being quite different, and while the flowers of the *Rodgersia* are produced when the leaves are fully developed, those of the other are produced in early spring and before the leaves begin to start. The flowers are rosy purple, and are borne in large round heads about the size of a closed hand, and are very pretty. The leaves are large, round, and attached to the stalk by the middle, on the under side, and shaped like an inverted umbrella, some of the larger ones holding as much as half a pint of water. A compost of nearly three parts peat to one of sand and loam suits this plant admirably, and if possible a partially shaded nook should be chosen.—M.S.

A SIMPLE MELON SUPPORT.

THE accompanying sketch represents the simplest and best means of supporting Melons which I have yet met with. Obtain a piece of any

Fig. 109.

hard well-seasoned wood about 5 inches wide, cut it into 8-inch lengths; bend some pieces of stout wire into those represented at *a* and *b*, and drive one into the centre of each end, and the thing is complete. It will be understood that the length of the hooked wire *b* must depend upon the angle of the roof on which it is to be suspended. Place the support on one of the wires as at *a*, and, holding it as near as possible level, measure how far it is below the next wire above that on which it rests, and make the hooked wire *b* to correspond. Fruit supported on these are nearer the glass than if they were suspended, and consequently they can with less trouble be fully exposed to the sun when ripening. No tying is ever necessary, as they can be placed on them as soon as they are "set," and the only after attention needed is—when the fruit begins to attain some size—to place two or three small pieces of wood round the fruit on the supports, to keep it from rolling while syringing, or should the wires get shaken while attending to the plants.—R. INGLIS.

BIG ROSES.

AS regards these I cordially agree with your valued correspondent, "C. P. P.," that size can never be a disqualification when the quality is maintained. Truly, if the larger specimen is the coarser let it go to the wall, but if we have equally fine quality with larger size let the larger win. Who, for instance, would object to one of the small but first-quality Pears being the size of a baking Pear, provided the grain and quality were equally free from coarseness? Certainly the eater would not. The whole of this question turns solely on the quality. I have not yet made acquaintance with Her Majesty, but am prepared to worship. If Her Majesty be Charles Lawson improved in form few Roses can be of a lovelier colour. Will Her Majesty, if of this large size, be a great acquisition to our stands? Well, I should say only under certain circumstances. It will not do in my humble opinion to place her in the back row even if the said bloom be very much larger than the rest of the blooms in the stand. Certainly the more even in size

the blooms are, being slightly larger towards the back of the box, the better, provided they are sufficiently large. Madame Noman is so exquisitely beautiful, and withal so rarely seen, that I do not wonder at any judge giving a stand of Madame first prize if they were good, but such a decision should not upset the present generally received opinion that size coupled with quality must carry the day, "J. A. W.'s" protest notwithstanding.

I will go every inch of the way, too, with "C. P. P." in praise of the beauty of A. K. Williams. That splendid Rose merits all that can be said of it as to beauty, and he is a worthy partner for Marie Baumann at the head of the Rose poll; but—aye, there it is, that wretched but. Well, I cannot help it, I write the truth as I find it, and here I write also the experience of several other friends in this district—gladly, very gladly should we like to find in the gentleman a little of the constitution of the lady. We had no winter we might say; we had some cold, very cold weather in May, but it seemed to me that the mischief had been done before. Anyway, plants not a few in this neighbourhood of A. K. W. are starting so feebly or not at all that one is forced to the conclusion that the constitution of the gentleman lacks very sadly the stamina to be found in the lady. I went into a friend's garden last week. "Look," was his remark, "look at the wretched exhibition A. K. Williams is making; that's all I can show out of a dozen plants. I fear he won't do here." And this is not a solitary verdict, and my own experience coincides with it. Very possibly this is only our "misfortune." I do not think it is our "fault;" but at any rate with us I believe we should all agree to doff our hats to the lady and give the highest place to her.—Y. B. A. Z.

ALPINE AURICULAS FOR THE GREENHOUSE.

THERE is a hazy undefined sentiment among gardeners as a class that florists' flowers are not worth growing; a state of feeling which florists themselves have perhaps contributed to in no slight degree. A florist of the strictest type defined the position he himself occupied as a cultivator—and it is a position that many others occupy—in these words: "I don't care," he said, "for flowers which cannot be critically examined and admired. A good Auricula I can spend a quarter of an hour over, but the flowers in common cultivation do not attract my attention at all." It must be conceded that it requires a period of educational effort to attain to the standard of our florist friend, and it is not perhaps desirable that all of us should be so critical in our floral requirements.

To those who like a showy flower of a refined type, no better subject can be chosen than Alpine Auriculas. Mr. Turner has effected such an improvement on these during the last ten years as to bring them within the range of everyday gardening, at the same time that the standard of the florist is more nearly approached. Fifty or a hundred well-grown specimens of the better varieties will make a feature in any garden well worth the little trouble attending their culture. I do not know any flower so easy to manage as these, or that attracts more attention. Plants in 5-inch pots are allowed to produce half a dozen large trusses, which, if not so showy as Cinerarias or Pelargoniums, are vastly more interesting and attractive.

The present is a very good time to procure a stock of plants, and though it is not possible to make a great show the first year, they will bloom sufficiently to give an earnest of what may be expected in the future. The newer varieties have nearly surpassed the older ones; but of the latter, Diadem, Sydney, Mercury, Bronze Queen, Colonel Scott, Mrs. Meiklejohn, are still worth growing; and the newer sorts, such as A. F. Barron, Mrs. Dodwell, Mrs. Llewelyn, Sensation, Topaz, Slough Rival, Mrs. Thomson, Philip Frost, and John Ball must also be grown. The easiest way to grow these is to plant them out in good soil from the end of May until the beginning of the succeeding February, when they must be lifted and potted and brought on in frames, again planting out when the flowering period is past. When growing all the year round in pots, the plants are best repotted immediately after they have finished blooming, shaking the soil from the roots in much the same manner as with Pelargoniums. Some of the older roots are removed along with the bottom portion of the so-called taproot. Any offsets ready are at once removed; though with a stock of established plants the easiest way to increase the number is to divide the larger plants into two portions and make each a separate plant. The soil suitable for Pelargoniums, Chrysanthemums, or Carnations will grow these equally well. Efficient drainage is a necessity, and firm potting is advantageous. After repotting, the plants require to be kept close and shaded for a fortnight or so; they only require the protection of a frame from extra abundant rainfalls.

As regards seeding the plants and raising seedlings, it will be found best to cross-fertilise the flowers. A much larger crop of seed is thus produced. It is simply managed by examining the plants set apart for the purpose with a camel-hair brush daily,

fertilising the flowers. Sow directly the seeds are ripe in pans filled with light soil; place them in a moist cool house shaded from sunshine, and the seedlings will soon appear. With ordinary care the seedlings will flower the second spring after the date of sowing. If good for nothing else these will be extra fine for borders and beds out of doors.—B.

LILIUM LONGIFLORUM VAR. HARRISI.

THIS is a most lovely plant, and of great value for growing in pots for conservatory decoration and for cutting for vase decoration. It can be forced easily, and with a sufficient number of plants a supply of bloom can be obtained for a lengthened period without a break. I am not acquainted with its history, and have only grown it this year for the first time. Some of the plants were grown in a cool stove from the beginning of January. These flowered about the end of April; others grown on in a cool house and taken into warmer quarters in March are flowering from the middle of May, with some to open at the end of the month. The compost which seems to suit them is fibrous loam, peat, and silver sand. In this they root very freely and take a large supply of water. The pots are standing among Ferns, so as to keep the roots as cool and damp as possible. I intend to have the plants in a cool house throughout the ripening period, and repot the bulbs after a good rest in October or November. Grown in 5-inch pots the strongest plant showed four flowers of the purest white.—B.

THERE is no doubt as to the superior value of *L. Harrisi*. In the autumn of 1882 I secured two batches direct from America, the sender of each batch claiming to have the "true variety," and upon examination of the bulbs I fancied there was a slight difference in one lot. The scales were very long and narrow, much longer at one end than the other, giving the bulbs an oblique form; in the other they much resembled the ordinary bulbs of *L. longiflorum eximium*. Each batch was potted separately and marked with the initial letter of the sender, and small lots of typical *L. longiflorum eximium* and *L. Takesima*, all direct from Japan the previous season, were potted with them with the idea of giving them precisely the same treatment, and as far as possible this was carried out; the result being that *L. Harrisi* were the first to bloom, *L. eximium* and *Takesima* (which are identical) second, and the normal *L. longiflorum* last.

I may mention that there were two distinct forms imported from America under the name of *L. Harrisi*, one proving, as far as my judgment could discern, nothing more than *L. eximium* both in flower, manner, and time of flowering; while the others were what I regard as the true *L. Harrisi*. It has a very erect habit, with narrow nearly erect leaves, thus differing from *L. eximium*, which has broader and deflexed leaves; the flowers of *L. Harrisi* are also longer and narrower in the tube, and the perianth divisions more recurved. In these particulars it differs materially from typical *L. longiflorum*, which has a much shorter tube, much dilated at the top. The bulbs of *L. Harrisi* are remarkably free, for before the first stems had finished flowering others were coming from the base. The result was that in September and October another good crop of blooms was enjoyed. I am referring now to its behaviour under pot treatment outside. I am not aware that any other form of *L. longiflorum* does this. The same bulbs are now in pots outside, and showing flower buds with additional strength. I have had some with four and five flowers, but cannot yet say how many will be produced this season. In this particular they do not differ from *L. longiflorum eximium*; the main difference seems to be in the habit, length of tube, and the repetition of blooming in the same season without resorting to forcing. More than one American grower informed me that it may be kept constantly growing, and will continue to bloom if the bulbs are repotted after flowering.

The history of this variety is obscure. It is said that it was introduced from Bermuda; probably it may have been, but it is more than probable that it was first introduced into that country from Japan, and it may be that owing to the most genial climate that the variety has attained its floriferous characteristics. It will be necessary to watch it for a few years to know if that feature is permanent, and as far as I know no Lily should prove more useful for decorative purposes. Upon one point I feel confident—viz., that *L. eximium* has often been substituted for the supposed true *L. Harrisi*.—J. T. R.

COSMOPOLITAN POTATO.—This is an excellent time, for the next few weeks, to compare the foliage and growth of different varieties of Potatoes

as long experience induces me to attach much importance to both. I have about thirty varieties growing side by side—early, intermediate, and late, many only introduced within the last few years, and it is very interesting to note their progress and appearance from day to day. The most remarkable of the whole is the above, and it certainly is the most promising. It is not a tall grower, but the leaves are as large as a Cabbage, and of a fine dark glossy green, much smoother than the majority of other varieties grown under the same conditions. Last year

now established that a visitor can fully rely upon finding abundance to compensate him for his journey. Numerous classes well filled with examples of the best culture must present something of interest, and possibly of profit too. If it were for one circumstance alone a southern cultivator would reap no inconsiderable benefit, and that is the genuine enthusiasm which prevails amongst our northern friends, a most pleasing unanimity amongst the promoters of horticulture, and an absence of petty jealousies that too frequently mar meritorious projects. The

Fig. 110.—LILIUM LONGIFLORUM VAR. HARRISI.

the tubers were large, but I had but a limited quantity, and kept most of them for propagation.—W. J. MURPHY, *Clonmel*.

NOTES AT MANCHESTER.

THE Whitsuntide Show at Manchester has gained a great fame throughout this country, and in consequence many horticulturists pay an annual visit to the great Cotton City, with the object either of contributing some of their productions or to inspect and criticise those of other members of the craft. So firmly is the reputation of the Show

result of this earnest combination of workers has been the institution and growth of the Manchester Show to its present magnitude and excellence, highly creditable alike to its organisers, its subsequent management, and its liberal supporters. As the veteran exhibitor, Mr. B. S. Williams, pointed out at the dinner on the opening day, this success is due in a large measure to a judicious liberality with the prize money, and to the generous encouragement given to amateurs, meaning thereby gentlemen or others who do not grow for sale. Undoubtedly this is a point of great importance, and the opinion, coming as it did from an experienced nurseryman, should have great weight with the

managers of horticultural shows. The fact is obvious, if the best amateur productions can be procured at a show the nurserymen will, in their own interest, soon be there. Experience, too, has proved that the prizes must be sufficiently high to guarantee to the winners ample compensation for their time and labour, for when the prize money was small at Manchester the Show was a financial failure, but since the amount has been so substantially increased the Shows have resulted in a most satisfactory balance. These are hints that the committees and secretaries of societies may ponder over with advantage.

THE PEAK DISTRICT ROUTE.

So it is that scores of gardeners and garden lovers wend their way northwards at the approach of the Manchester Show, and with the majority the favourite route is the Midland line, which passes through the beautiful peak district of Derbyshire. I have travelled over this line many times, but on each occasion this portion of the journey presents something fresh and picturesque, and if the traveller be favoured with sunny weather a more charming ride could not be desired. It is especially enjoyable by those who are accustomed to the quieter beauty of our southern counties with their modest gently rounded hills and extensive commons, or level meadows, for in the Peak district we get a miniature representation of some of the great Alpine regions. After passing Derby when going northwards, until arriving at Marple, the scenery is most varied, always beautiful, and sometimes grand in the extreme. Dashing through a tunnel we are the next moment upon an embankment perhaps 100 feet high, commanding extensive views of deep winding valleys, with a rocky watercourse at the bottom, lofty hills sometimes densely clothed with trees and shrubs from base to summit, and other times rigid, cold, and bare, except for the scanty grass which manages to find subsistence almost on the bare rock. Again, perhaps, is seen a steep escarpment, upon which the action of the weather is plainly visible, the slopes and valley below being covered with the separated portions, sometimes tons in weight, forming geological lessons of considerable interest. Especially beautiful is the district between Chapel-en-le-Frith and Buxton, and near the former station is a grand amphitheatre of hills, rising at several points into sharp peaks far above the others, and enclosing a charming valley, through which a small river can be seen dashing over its stony bed. There is much to admire of a similar character along the entire route, thoughts of which the traveller will bear with him amongst the most pleasant memories of his visit.

THE ORCHIDS.

At the Old Trafford Gardens a great surprise awaited all arrivals in the magnificent Orchids which occupied so large a space in the exhibition house. These plants have for several years been admirably represented at the Whitsuntide Show, but never has so large a display of such grand specimens been seen there. It was estimated that the total value of all the plants in the Exhibition was not less than £20,000, and of this the Orchids alone would have formed a large proportion; for one specimen, Mr. Percival's unrivalled *Cattleya Mendeli*, has been valued at £300. About 220 specimen plants were contributed, and many of these could not be equalled in the kingdom. Mr. Percival's Orchids were, of course, the great feature, such large, vigorous, and profusely flowered examples being rarely seen either in exhibitions or private gardens. The *Cattleya* above mentioned and *Laelia purpurata* with eighty flowers were superb, and proved conclusively how well their culture is understood at Southport. Dr. Ainsworth's *Phalenopsis amabilis* with forty spikes, or a total of about 200 flowers, was another specimen of special note; while Mr. J. Broome's *Vanda teres*, 5 feet in height with fifty spikes and about 200 blooms, was another grand example of culture. These were a few of the leaders amongst an army of amazonian beauties which excited the astonishment of many visitors and the admiration of all.

MR. JOSEPH BROOME'S PLANTS.

Since the establishment of the Manchester Botanical and Horticultural Society, Joseph Broome, Esq., of Wood Lawn, Didsbury, has taken an ardent interest in its welfare, and has endeavoured in every way to contribute to its success. As Vice-President he has been enabled to still further assist the Council and Curator both by his advice and by more substantial pecuniary support. His large collections of plants, too, have repeatedly added greatly to the attractions of the exhibitions, but never has he exhibited so largely or successfully as at the recent Show. Orchids, Crotons, Dracaenas, Pitcher Plants, Ericas, new plants, Sonerilas, herbaceous and alpine plants, with Pansies and Violas, furnished attractions in every tent, and throughout the plants were marked by a fresh healthy appearance indicating the best attention. Particularly fine were the *Nepenthes* and *Sarracenias*, which I have never seen equalled at any exhibition. *Nepenthes Mastersiana* is gradually gaining favour in gardens, and such magnificent examples as that from Wood Lawn, with ten massive richly and uniformly coloured pitchers, will aid materially in increasing its popularity. It is indeed a handsome species, the dark red colour being so rich and distinct. *Nepenthes bicalcarata* from the same garden, fully 6 feet in height, growing with the utmost luxuriance and bearing a dozen of its gigantic pitchers, is probably unique. The well-known *N. Rafflesiana* was loaded with well-coloured pitchers; and the *Sarracenias*, 2 and 3 feet in diameter, grandly coloured, especially *S. purpurea*, which was magnificent in every respect. *Sonerilas* are charming little plants, but are rarely exhibited and too seldom grown as they should be, Mr. Broome's collection includes some of the most distinct and pretty, grown in shallow pans, their neatly marked leaves coming well coloured in a light position of a warm house. The herbaceous and alpine plants showed the same good culture and neat correct labelling which have been

previously commended in these pages on several occasions, the other miscellaneous contributions being equally creditable. A few such wealthy and liberal supporters as Mr. Broome insure a large share of success, and the Society is fortunate in having obtained his assistance.

It may be added that the garden at Wood Lawn, though not extensive, is in some respects a model one, thoroughly well kept in every department. The outdoor beds, borders, and rockeries are well stocked with the choicest and most effective of hardy, herbaceous, and alpine plants, the houses being similarly filled with tropical plants. One house, or rather a corridor, merits, however, a special note. This is kept bright and attractive throughout the year by the most ornamental herbaceous plants, which are grown in pots for the purpose and transferred to the house when required. Some extremely pleasing displays are thus produced, and by a judicious selection of species and varieties it is surprising how well a constant succession of bloom can be insured. It is simply a conservatory of hardy plants, and the plan might well be more generally adopted, as there are many beautiful, but slightly tender, plants which are rarely seen at their best in the open border, whereas under glass their flowers can develop uninjured.

MESSRS. W. & J. BIRKENHEAD'S FERNS.

The charming group of Ferns from this firm was one of the features of the Exhibition, a most tasteful combination of elegant foliage and varied shades of green. Examples of this style of grouping plants have for several years been prominent at Brighton and Eastbourne Shows, where classes are specially provided for them; but the idea does not appear to have extended beyond these Societies. Messrs. Birkenhead therefore set a bold example in entering the class for a general group of plants with one composed exclusively of Ferns. It was, however, so greatly admired that it is to be hoped that some special encouragement will be given to this form of grouping.

A large number of species and varieties were represented in the group, but to gain an accurate idea of Messrs. Birkenhead's stock a visit must be paid to their Fern Nursery at Sale. There the Fern-lover will find ample to interest him, for some seventeen or eighteen houses are devoted to these graceful plants, forming probably the largest collection of Ferns in cultivation. All the best-known and generally useful species of both hardy and exotic Ferns are grown in thousands, and a glance at the house of sporelings ready for potting occasions a feelings of wonderment as to where they will all find homes. There certainly appears to be enough to stock the entire country, yet Messrs. Birkenhead occasionally find it difficult to meet the demand for some particular species. At this time of year, when the majority of the plants are making fresh growth, their appearance is especially beautiful, their bright green elegant fronds rendering the houses very attractive. In every department the Ferns are distinguished by a robust healthiness that is most refreshing, and there is an absence of that drawn flaccid flimsiness which too often characterises Ferns in private gardens. One cause of this greater sturdiness is the practice of exposing the plants freely to light without going to the extent of permitting the young tender fronds to be injured by bright sun. What might be termed the "dark" system of culture has too long been followed with Ferns, and the result is that in many establishments plants may be seen dragging out a miserable existence, unsatisfactory alike to gardener and employer. There is, however, a gradual awakening to the fact that Ferns, like other plants, do not under cultivation require to be perpetually in a state of semi-darkness, and with better houses, stages, or shelves nearer the glass, and more liberal ventilation in suitable weather, the plants are more likely to develop their true beauty and proportions. Another matter which has been fully proved in the Sale Fern nursery is that peat is by no means so necessary for Ferns as has been so long supposed, better and more substantial growth being obtained from Ferns in a compost of good loam and leaf soil than from the best peat obtainable. Indeed, there are some Ferns, and amongst them may be mentioned the *Scolopendriums*, which thrive best in a rather heavy loam. The supply of moisture is of great importance, and the soil in which a Fern is growing should never be allowed to become dry. At the same time Messrs. Birkenhead and many other growers find that syringing Fern fronds is to a large extent better avoided; in many cases it is of doubtful benefit, and in some it is positively injurious. Preserve the requisite amount of moisture in the air by damping paths or stages, but beyond an occasional sprinkling to keep the fronds fresh and clean do not syringe them. Such in brief is their practice, and the proof of its suitability is apparent in the condition of the plants.

To enumerate only the best of the species and varieties composing the Sale collection would fill a volume; all the leading genera are strongly represented, and there are some varieties which it would be difficult to find in any garden in England. Those little gems the *Cheilanthes*, *Nothochlaenas*, and *Pellaeas* are especially numerous, and succeed most satisfactorily on a shelf close to the glass in a small lean-to house. These charming little plants are reputedly difficult to grow, but there they appear quite at home, producing their graceful prettily powdered fronds most freely.

They are seldom seen in gardens, chiefly no doubt because there is an impression that they will not succeed; but those who have seen the Sale collection will be inclined to alter any unfavourable opinion that they might have formed. There the plants grow freely, unfurling their charmingly graceful fronds, and soon forming on the shelf devoted to them quite a thicket of growth. An especial favourite is the so-called Lace Fern, *Cheilanthes elegans*, with its finely divided fronds, which needs a rather warmer position than most of the other species, such as *C. Cleve-*

landi, C. Fendleri, C. frigida, C. myriophylla, and C. vestita, which succeed best in an ordinary intermediate Fern house. The *Nothochlænas* are similarly divisible into two classes, the warmer section including *N. chrysophylla*, *N. nivea*, *N. rufa*, and *N. sinuata*; while in the cooler group we have *N. canariensis*, *N. candida*, and *N. lanuginosa*, all pretty species, but little known.

In every house there are numberless attractions—*Adiantums* and *Aspleniums* in abundance, with scores of varieties over which a Fern-lover would go into ecstasies. In addition to the usual tropical Ferns there is a good collection of the best "Filmies," which, like all the others, are in most satisfactory condition. The hardy Ferns are grown in hundreds of thousands, and more vigorous specimens I have never seen in cultivation. The beautiful little Beech and Oak Ferns, everyone's favourites, are very strongly represented; while the most distinct and handsome of the varieties of British Ferns are grown in abundance. Throughout the collection is most interesting, and no horticulturist should visit Manchester without spending an hour or two at Sale.—LEWIS CASTLE.

EXHIBITING CARNATIONS.

IN answer to Mr. Douglas at page 451, I beg to state that my information came in this way. While admiring the stands at some of the Carnation Society's shows, other lookers-on, and apparently without any concealment of their remarks, freely gave expression to their convictions that the majority of the flowers in the small winning stands were not grown and prepared by the exhibitors of them, but that they were obviously the production of a larger and more experienced grower. I am positive of the truth of what I stated—namely, that such "remarks" were prevalent. Beyond that I made no assertion, and I had no other object in asking a question thereon than to "elicit truth." It is open for other exhibitors to make a statement as plainly as Mr. Douglas has done; and his letter I look upon as an invitation, if not a challenge, for them to do so. Can all the great growers say they "never gave nor lent a flower to anyone else to exhibit," nor permitted any flower to appear in other stands than their own? And can they also assert that they have "no knowledge nor reason to suppose that their flowers have appeared in other persons' stands?" Next, can all the winners in the smaller classes state plainly and unequivocally that they "never staged a flower that they did not grow themselves in their own gardens? At present an opinion undoubtedly exists that flowers in both the larger and smaller classes were the products of the same grower. Is this so or is it not? I write for information solely on matters of unquestionable public importance, and which one of the leading officials of the Society asks for in a public manner. I am a deep lover of the flowers in question, and should like to see the removal of every possible impediment to the increase of cultivators and exhibitors. One word more. Personal differences are known to exist between florists, and some readers may suppose that I have some small grievance against someone or other connected with the Society. This is most certainly not so. I have never had the smallest difference with any exhibitor or member of the Society, but I deal with the matter exclusively on its merits as a question of public interest to florists and horticulturists, and as a perfectly proper subject for discussion in the horticultural press.—ONWARDS.

ROYAL HORTICULTURAL SOCIETY.

JUNE 10TH.

PYRETHRUMS and miscellaneous hardy flowers constituted the great attraction at Kensington on Tuesday last, and rarely has a more extensive and beautiful display of these plants been contributed. The conservatory presented a charming appearance, and was thronged with visitors during the afternoon. The majority of the groups will remain on view during this and the following week.

FRUIT COMMITTEE.—Present: Henry Webb, Esq., in the chair; Dr. R. Hogg, H. J. Veitch, H. Burnett, G. Paul, J. Roberts, G. Bunyard, J. Smith, G. T. Miles, S. Lyon, W. Paul, P. Crowley, R. D. Blackmore, and J. Lee. Messrs. Richard Smith & Co. of Worcester sent a seedling dessert Apple resembling the Birmingham Pippin, which was not considered to be of great merit. Mr. George Ashlett, gardener to R. Butler, Esq., Manor Wood, Hatfield, sent a dish of Royal George Peach. Captain Leblanc (gardener, Mr. May), Northau House, Barnet, sent a fruit of Melon Masterpiece, a pretty-looking golden and netted-skinned Melon, which was inferior in flavour in consequence of being too far gone. J. N. Hibbert, Esq. (gardener, Mr. Herrin), Chalfont Park, Gerrard's Cross, sent a seedling Melon Chalfont Favourite, a pleasantly flavoured fruit, but rather thin in the juice. It is peculiar in being a green-flesh with a red lining next the seed. A letter of thanks was awarded. J. Thompson, Esq. (gardener, Mr. Parker), Oakfield, South Edin Park, Beckenham, sent a pair of Cucumbers united by the process of fasciation.

FLORAL COMMITTEE.—Section A.—Present: Thomas Moore, Esq., in the chair; J. Fraser, J. Laing, F. R. Kinghorn, Rev. G. Henslow, H. Williams, J. Doniny, J. Woodbridge, E. Hill, J. O'Brien, H. Ballantine, and Dr. Masters. Section B.—Present: Shirley Hibberd, Esq., in the chair; J. James, W. Bealby, G. F. Wilson, G. Duffield, W. B. Kellock, H. Bennett, H. Cannell, and J. Douglas.

Hardy flowers from Mr. T. S. Ware, Tottenham, formed a beautiful and interesting group, representing a large number of choice useful plants for the outdoor garden. Such displays as this do much to popularise hardy flowers, as no collection is so greatly admired by the visitors; the diversity of colours and forms is surprising to many who have little idea of the abundance there is now to choose from. Irises were well shown in all their numerous shades of blue, purple, yellow, and bronze. Ixias were also in strong force, the shades of rose and crimson being especially beautiful. Very notable were the varieties Glory, bright rose; Lady Slade, soft pink;

Lady of the Lake, crimson; crateroides, rosy crimson; Sarnia's Glory, yellow striped with rose; rosea, of an exceedingly bright rose tint, and the peculiar green viridiflora. The Poppies were attractive, especially the neat-flowered *Papaver nudicaule*, of which two excellent varieties were shown—i.e., *mini-atum*, bright orange-scarlet, and *album*, pure white. Pyrethrums, Aquilegias, and Pansies were largely represented by selected varieties, and amongst other notable plants were the following: The Water Hawthorn, *Aponogeton distachyon*; the yellow Day Lily, *Hemerocallis flava*; the dense dark purplish-blue Bellflower, *Campanula glomerata dahurica*; the pretty Horned Poppy, *Glaucium luteum*; the rich rose-coloured *Lychnis viscaria splendens plena*; the scarlet Larkspur, *Delphinium nudicaule*; *Lilium tenuifolium* and *L. bulbiferum*, the former with neat orange-scarlet flowers, and the latter with larger, paler, orange-tinted blooms; the Golden Columbine, *Aquilegia chrysantha*; the handsome rose-and-white Lady's Slipper, *Cypripedium spectabile*, and the pretty rose-tinted *Allium Ostrowskianum*. In addition there was a large collection of varieties of *Ranunculus asiaticus*, richly and diversely coloured neat little globular flowers of great beauty. The Council awarded a silver-gilt medal for the group, an honour which it well deserved.

Irises formed the principal feature in the collection of hardy flowers from Messrs. Barr & Son, Covent Garden, and a good idea of the beauty of these plants at this time of year from the specimens of the different sections exhibited. The Iris neglecta group includes a large number of varieties, some of the best being Victorine, with purple falls and white standards; Rolandiana, with violet-streaked falls and purple standards; Hannibal, with purple-veined falls and mauve standards. The Spanish Irises with their yellow, bronze, and purple flowers were very striking, one of the best yellow selfs being California. The blue and purple English Irises were similarly beautiful; the curiously coloured *I. squalens* and its varieties furnished another attraction, and *Iris versicolor kermesina*, with crimson purple-veined falls and pale nearly white styles, was charming. *Iris variegata*, *I. aphylla*, and *I. pallida* were also noteworthy in one of the finest collections of early Irises that have ever been shown. Grand blooms of the large *Papaver orientalis maculatus*; Pyrethrums in many varieties, both single and double; Scillas, and other attractive plants, completed this group, for which a bronze Flora medal was awarded.

Handsome groups of Irises, Ixias, Aquilegias, and Stocks were also exhibited by Messrs. J. Veitch & Sons, Chelsea. Both the former included numerous fine varieties. Two English Irises—namely, *Alba grandidissima*, pure white, and Prince of Wales, blue with purple standards, were remarkably good, the Spanish varieties also comprising several notable forms. Hybrid Aquilegias were much admired for their pretty colours and graceful forms; the shades most represented together were white and blue, yellow and white, with yellow and red. The scarlet Brompton Stocks were very handsome, with enormous dense spikes of large brightly coloured flowers; seldom indeed are these fine old plants seen in such perfection, and Messrs. Veitch evidently have an excellent strain of seed. A bronze Flora medal was awarded for the group.

Pyrethrums were superbly shown by Messrs. Kelway & Son, Langport, fourteen boxes being staged, each with sixty blooms of a dozen varieties. The boxes of double varieties were placed at the back, the single varieties occupying the foremost position, where the superior brightness of their colours could be seen to the best advantage. These lovely plants are extremely effective, and now such a diversity of colours has been obtained they should be grown everywhere.

A great number of good varieties were included in this fine collection, but the following are the most distinct under the several colours. It is, however, to be regretted that so many obscure classical names should have been chosen for the plants, as it will militate considerably against their popularity.

Single Varieties.—Magenta and Crimson: Marcius, Rhodus, Aculum, Favorius, Ophias, Rubi, Almanzor, Theodotus, Nero, Menandra, and Genesus. Rose: Abacena, Devona, Nanus, Belarius, Amaryllis, Cerinthus, Babyrsa, Celelates, Sabatium, and Vestatis. Blush: Abderites, Muta, Abarinion, Abradatus, Barkis, Acacisius, and Alexas. White: Marica, Blucium, Sabus, and Nisbola.

Double Varieties.—Crimson: Captain Boyton, J. M. Twerty, Rembrandt, Capt. Nares, Gloire d'Italie, and Galop. Rose: Iveryana, Progress, Duchess of Edinburgh, Marquis of Salisbury, Floribundum plenum, and Ros' Perfection. White: Princess de Metternich, Carneum plenum, Penelope, Mont Blanc, and Niveum plenum. Yellowish: Solfaterre and Cleopatra. Blush: Peach, Mons. Duvivier, Lady Derby, La Vestale, Lady Derby, and Virgo.

In addition some boxes of semi-double Pyrethrums were shown, the centre of the blooms being very full and globular, with an outer row of broad florets much brighter than in the ordinary doubles. Some fine Poppies and Pæonies were also included, and in the opinion of many persons the exhibit merited a higher recognition than the bronze Flora medal awarded for it.

Calceolarias formed a pretty group from Mr. Rapley, gardener to W. Brand, Esq., Bedford Hill House, Balham, the blooms being fine, richly and diversely coloured. Very notable was the handsome yellow self Cloth of Gold, which is remarkable alike for its strong habit, large flowers, and constancy. A bronze Banksian medal was awarded. A vote of thanks was adjudget to Messrs. Hooper & Co., Covent Garden, for a handsome collection of Pæonies and *Lilium Harrisii*, the former flowers being very large and richly coloured.

Amongst the miscellaneous new plants and flowers very notable was a collection of fancy Pansy blooms of the Rainbow strain from Messrs. Cannell & Sons, Swanley. These were extremely beautiful, the predominating colours being blue, purple, maroon, and gold, charmingly varied and combined. A vote of thanks recognised the merit of this exhibit, and a number of fine double tuberous Begonia blooms, the scarlet and rose shades of which were especially good. Messrs. J. Veitch and Sons sent several new plants, of which the most noteworthy were *Weigela hortensis nivea*, a charming white-flowered variety, wonderfully free and early, that will undoubtedly become a great favourite for forcing. With it was shown a dark claret red-coloured form of *Weigela* named Dr. Baillon, which is also very distinct. *Gloxinia Flambeau* is one of the richest scarlet varieties that has yet been obtained, the flowers being of moderate size, but produced in great numbers. *Metrosideros floribunda alba*, a white variety of the well-known beautiful Bottle-brush tree, was

shown by Mr. B. S. Williams, Upper Holloway. The plant was compact in habit, about 3 feet high, and bearing twenty or more long spikes of white flowers. A vote of thanks was awarded for it. Mr. R. Dean, Ealing, sent flowers of a peculiar reddish-coloured *Lathyrus* named Drummondii, something of the fashionable so-called "crushed Strawberry" tint. Mr. Hill, Tring Park Gardens, was awarded a cultural commendation for a well-grown specimen of *Cattleya gigas* with ten flowers, having richly coloured lips much like *C. Sanderiana*. A vote of thanks acknowledged a panicle of *Oncidium Marshallianum giganteum* from G. N. Wyatt, Esq., Lake House, Cheltenham, a grand variety, which was certificated at the recent Manchester Show. It is remarkable for the great size of the lip, which is over 2½ inches broad, the colour being also good.

Votes of thanks were also accorded to J. Gair, Esq., The Kilns, Falkirk, N.B., for a few *Cattleya* and *Dendrobium* flowers; to Mr. J. Stevens, Putney, for flowers of *Abutilon* Lustrous, a rich shining red variety; to Mr. James, Farnham Royal, Slough, for a collection of richly coloured handsome *Calceolaria* flowers, which also were highly commended; to Mr. Woodbridge, The Gardens, Syon House, Brentford, for flowers of *Ornithogalum caudatum*; to Messrs. Paul & Son, Cheshunt, for Tea Rose Souvenir de Thérèse Levet, a bright red fragrant variety of dwarf habit, to J. Leeson, Esq., Crosslands, Furness Abbey, Barrow-in-Furness, for a plant of a seedling *Hydrangea* with large flowers, said to have been obtained from a cross between *Thos. Hogg* and *variegata*; and to Mr. Stacey, Dunmow, for a collection of brilliantly coloured large-flowered *Verbenas*, a most valuable strain for bedding or culture in pots.

First-class certificates were awarded for the following plants:—

Odontoglossum crispum Souvenir de Prince Leopold (Sanders).—A handsome variety, with massive grandly formed flowers 4 inches in diameter; the petals 1½ inch broad, white with a few brown dots on the lip, and a purplish tinge in the sepals. Beautiful as it was, however, we have seen varieties equally as good and better from the same firm. The adoption of such names as the above should also be discouraged by the Committee.

Odontoglossum crispum roseum guttatum (Sanders).—Very distinct, the flowers large and symmetrical, with a rosy purple tinge in sepals, and pale brownish spots. A charming variety, well worth the honour bestowed upon it.

Tuberous Begonia Lucie Lemoine (Cannell).—A neat double variety, with full creamy yellow flowers. Free and compact in habit.

Tuberous Begonia Madame Castaigne (Cannell).—An effective double variety, with massive bright rose-coloured blooms. Very handsome.

Tuberous Begonia Canary Bird (Laing).—A double yellow variety, which was some time ago certificated both at Regent's Park and the Crystal Palace.

Verbena Lord Brooke (Mr. H. Stacey, Dunmore).—A superb variety, with flowers of great size, over half an inch in diameter, and good form, brilliant scarlet, with a white centre. Truss compact, habit free.

Kalmia latifolia major splendens (Veitch).—A fine variety of this well-known shrub, with larger and better-coloured flowers than usual, the buds being quite of a scarlet hue, and the expanded flowers bright red fading to white.

Statice candelabra [S. Suworowi] (J. Carter & Co.).—A second-class certificate was awarded for a *Statice* under the above name, which is the same as that which has been recently exhibited as *Statice Suworowi*, figured in the "Gartenflora," and described in the "Gardeners' Year Book" for 1884. In good condition as it was shown at Manchester this plant is extremely handsome and distinct, with close cylindrical spikes of pale rosy flowers a foot or more in length. In the specimen certificated the spikes were from 6 to 9 inches long, branching at the base. The leaves are coarsely toothed and rather small.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Æcidium Berberidis and *Uredo and Teleuto Spores on Wheat*.—Mr. Plowright sent an interesting communication, giving an account of Schöler's discoveries in 1807, a Dane, who by experiment was convinced that the Barberry blight caused the rust in Wheat, though his conclusions were not accepted by the botanists of the day. Specimens of Wheat were sent showing abundance of *Teleuto* spores (black mildew) after impregnation by *Æcidium*, and others with abundant *Uredo* spores (red rust) from Australia, and not arising from the *Æcidium*. These conditions Mr. Plowright asserts are characteristic of their respective origins. The communication will appear in the *Gardeners' Chronicle*.

Ræstelia lacerata on Hawthorn.—Mr. Plowright also sent specimens of Hawthorn badly infested with this fungus, and which had been artificially produced. He had applied on 24th April the spores of *Podisoma* growing on neighbouring Juniper bushes to the Hawthorn; subsequently the *Spermogonia* appeared, which were followed by the perfect *Ræstelia*. This interprets the supposed "canker" which was sent to the Scientific Committee on a previous occasion.

Tuber-bearing Rootless Cuttings of Solanum Commersonii.—Mr. Burbidge sent specimens of cuttings with a communication describing how they never rooted, with one exception, while the roots in that case sprang from a new shoot out of an axil, but all of which produced tubers from the lowest axils. The foliage had become yellow in every case. The communication will appear in the *Gardeners' Chronicle*.

Plum Attacked by Caterpillars.—Mr. Henslow showed a branch badly infested with *Hypnometra* larvæ.

Wallflower Growing in a Currant Stem.—Mr. Murray reported on this specimen exhibited at the last meeting. He said the pith of the Currant stem had quite decayed away, with the exception of that on the circumference, which had become converted into cork. The stem of the Wallflower, not the root, was only visible in the centre of the pith, and this had produced very little cortex, and had no epidermis. There were very few bark cells. The root must have penetrated to the stem of the Currant below the surface of the earth.

Rubus idæus var. *Leesii*.—Dr. Masters showed specimens of this variety, mostly with single leaves and small inconspicuous flowers. It has been supposed by some to be a hybrid between Raspberry and Strawberry. It is more probably a hybrid between *R. idæus* and *R. cæsius*. The pistil is distorted, but the pollen is perfect.

Bulbous Leeks.—Dr. Masters also exhibited specimens of Leeks with

bulbs. They came up in rows of Leeks sown from ordinary seed, and are probably reversions to the ancestral form.

Pseudolarix Kämpferi.—He also showed dried specimens of the male inflorescence, and cones remarkable for their fleshy or herbaceous scales and glaucous hue.

Malformed Strawberry.—Mr. MacLachlan exhibited specimens of Strawberry plants, in which the leaves and flowers were much distorted. The former had thick fleshy petioles and more or less aborted blades, while the essential organs of the flowers were apparently entirely arrested. Mr. MacLachlan thought it might be due to an acarid, to which *Potentillas* are subject. It was referred to Dr. Masters for examination and report.

Lilies Injured by Frost.—Mr. G. F. Wilson showed some Lily stems, which when 3 feet high were cut down by the frost, the stems being bent, but had since recovered, though they had not blossomed.

Beans Attacked by Weevils, &c.—Mr. Murray described some specimens which had been examined by Mr. Carruthers and himself, and which were found to have galls produced by weevils in the roots as well as Anguiluke. The latter had probably mainly caused the death of the plants.

Begonias with Malformed Essential Organs.—Sir J. D. Hooker showed blossoms some of which had no ovaries, although style and stigmas were present. In others the styles were antheriferous at the base.

Ornithogalum caudatum (?).—A fine plant sent from Syon House for name. It was referred to Kew.

British Orchids.—Mr. Horsefield sent a number of remarkably fine specimens of Orchids from Heytesbury.

Rhododendron fastuosum Malformed.—The Rev. G. Henslow exhibited blossom of a *Rhododendron* showing a tendency to doubling, but in which the pistil was open and flower buds appearing from within. He exhibited similar blossoms from the same bush in 1882, but it bore no flowers in 1883.

"Vegetable Generation" as Conceived in 1758.—He showed a small work by Dr. J. Hill with good plates, in which the author had convinced himself that pollen grains produced germs which crept down tubes in the style and entered the ovular "shells" prepared for them, thus considering the anthers to be female. Linnæus of the same date thought the anthers emitted a "seminal air," which was absorbed by the moisture of the stigma, and remarks that Morilandus believed the pollen to enter the germen; while he says that Needham confirmed his own opinion.—(*Philosophia Botanica*, p. 91 1783.)

GREENHOUSE RHODODENDRONS.

It is surprising that these lovely flowers are not more common. In some gardens we may find a single plant, but not more than two or three. A full collection is rare, and healthy specimens are seldom seen. In fact, altogether I am inclined to think that comparatively few know what floral gems the greenhouse Rhododendrons include. There are no greenhouse plants, not even the *Ericas* and *Azaleas*, so exquisitely beautiful as the Rhododendrons, and when some of the best are in bloom they have an attraction far beyond that which any common plant can command. This is especially the case with such magnificent species and varieties as the Countess of Derby, Countess of Haddington, Jenkinsii, Lady Skelmersdale, Nuttalli, Princess Alice, Taylori, Pink Beauty, Virginala, and many others of the most delicate colours and sweetest odour. Unlike many of the open air varieties, the greenhouse Rhododendrons bloom profusely when quite young and small. Of late we have had some plants of *R. fragrantissimum* and others not more than 15 inches high bearing many fine trusses and splendid blooms, and large specimen plants are lovely when compactly grown and profusely flowered.

There are two ways of growing them successfully—one is to plant them out in beds, the other to keep them in pots or boxes. In all cases the soil in which they are grown should contain a liberal quantity of peat and sand. Good drainage and firm potting must be practised. When making their growth the temperature of any ordinary greenhouse suits them. Water must be applied to them unsparingly both at the root and through the syringe. When the growth is completed and the flower buds formed, a drier temperature with less moisture is best for them. Plants may be taken into the open air in August and September to mature their growth, and shading should not be resorted to at any time. When well developed they are readily forced in the spring months, but they come best when not forced too quickly, and there is no season at which they bloom in such perfection as about Easter. Those who have no knowledge of their culture and would like to try them would not make any mistake by treating them in the same way, and in company with their greenhouse *Azaleas*.—M. M.

POPPYWORKS.

THE Horned Poppies are a very small family of plants, but are none the less interesting on account of their limited numbers. We claim at least one of them as our own. The plants are found on some of our seacoasts, and when seen in their native homes have a very striking appearance. *Glaucium luteum* is covered with a fine glaucous hue, and has dew-like bespangled sea-green leaves, which give the plants a very ornamental appearance. The whole plant abounds in a yellow juice, which is very foetid and possesses poisonous properties. *Glaucium luteum* is an attractive seaside plant. The flowers are very short-lived, but are produced in rapid succession, affording a fine display for a long time. The flowers are succeeded by a large seed pod often a foot in length, having the form of a horn, hence the appellation of Horned Poppy. The plant requires room to develop itself in cultivation, when it often attains the height from 2 to 3 feet. When well grown in the border and

shrubby the plants are very effective. They can also be turned to good account for edging or bedding purposes as white-leaved plants, but to have them dwarf for this purpose the flower stems must be pinched out. *Glaucium fulvum* is much the same in appearance, having somewhat deeper-coloured flowers. *G. Fisheri* is the most attractive from its having much deeper-coloured flowers, nearly approaching an orange colour.

The plants are easily increased by seed sown as soon as ripe. The seedlings appear in the autumn, and flower early in the following season. When sown in spring the plants flower in the autumn. They are also increased by side shoots taken off with a heel, smoothed with a sharp knife, the cuttings being inserted in sandy soil in well-drained pots, and placed in a cool shaded pit or frame. The plants thrive in any ordinary garden soil, but are the better for liberal treatment. They are regarded

Fig. 111.—*Glaucium luteum*.

by some as biennials, but I have had them last for years, and I cannot but regret that they are so seldom seen in cultivation.—V.

SOY BEANS.—The extensive use by the Chinese of this leguminous seed (*Glycine Soja*) is only recently beginning to attract attention. The following is from the proceedings of the Agri-Horticultural Society of India, January 5, 1883:—"The large white Pea is deserving of notice, since it forms the staple of the trade of Changhair or nearly so, to the astonishing amount of ten millions of dollars, or two and a half millions sterling. The Peas are ground in a mill and then pressed in a somewhat complicated, though, as usual in China, a most efficient press, by means of wedges driven under the outer part of the framework with mallets. No description would suffice without a drawing. The oil is used both for eating and burning, more for the latter purpose, however, and the cake packed like large Gloucester cheeses, or small grindstones in circular shape, is distributed throughout China in every direction both as food for pigs and buffaloes, as also for manure." Specimens of the Beans, as well as of the oil and one of the cakes weighing about 60 lbs., may be seen in the Museum of Economic Botany of the Royal Gardens.—(*Kew Report*.)

HARDY FRUIT GARDEN.

Pruning.—Midsummer will soon be here, and in order that the full strong growth which follows it should be turned to good account let arrears of pruning both of lateral and leading spring growth be speedily finished. It is difficult at this busy season of the year to devote enough time to the careful selection of fruiting wood for next year on Peaches and Nectarines, and consequently by far too much wood is often retained and crowded together upon the trees, only to be removed in the winter pruning. This wasteful process cannot be too often deprecated, for the wood which

is eventually retained is neither so strong nor can it bear such fine fruit as it ought. A fruit tree is cultivated solely for its fruit, and therefore no branch or shoot should be retained upon it, or, rather, be allowed to grow at all, if it does not in some way contribute to the desired end. Red and White Currants have now had all the spur growth nipped off to two or three leaves, the leading growth shortened, and if against wall or trellis at once fastened to it. If this is not promptly done many leading shoots are liable to be broken off by the first storm, to the disfigurement of the tree and the loss of the year's growth.

The Fruit.—Thin all crowded fruit of Peaches, Nectarines, and Apricots without further loss of time if it is not yet done. Especial care should be given to thinning clusters of Pears on all wall trees, the finest fruit being invariably produced by them. Do not, however, thin till the fruit is set and swelling, so that you may be able to see clearly whether thinning is or is not necessary. The Fig crop is so abundant that care must be taken to loosen the branches nailed or tied closely to wall or trellis, or much fruit will be spoilt by growing to instead of from the wall, and being pressed and deformed between and behind branches. Gooseberries used while green should be picked from the lower branches, and where they are left upon that part of the bush to ripen, drooping branches should be raised upon supports high enough to keep the fruit clean. Strawberries ought now to have litter or supports to keep the fruit from contact with the soil and from becoming splashed with it by heavy rain. Tiles or pebbles are best for laying under the fruit, because it is not apt then to spoil quickly in wet weather. Reeds and straw are the next best materials provided the straw is fresh, clean, and not saturated by anything offensive. Long grass answers well in dry weather, but in a wet summer fruit both ripe and green soon decays if resting upon it.

FRUIT-FORCING.

Figs.—Figs in Pots.—These as generally seen do not last long in bearing, nor produce a great number of fruits at one time, but when they have attained a height of 6 or 8 feet, and thoroughly established in pots of 18 inches or more in diameter, they then give a harvest of fruit of a very satisfactory character. At the present time the succession crop on the November-started trees will be swelling fast, and some of the most forward are ripening. In order to increase the size of the fruits the spring growths, which will in most cases be profusely set with fruit, and should be given a good thinning, and those ripening will be fine in flavour, according to the light, heat, and ventilation they receive. Throughout the growing season liberal feeding is absolutely essential, and the quantity that trees of the size above indicated will take is enormous, or from 4 to 6 gallons every alternate day. The liquid not only feeds the roots, but the ammonia arising therefrom, along with the copious syringing, keeps the foliage in a clean healthy state, free from insects, and the fruit does not fall prematurely. Should red spider appear syringe with clear sulphur water, but not until late in the afternoon or evening.

Fig Trees Planted Out.—Trees in inside borders and trained over a fixed trellis should have the shoots tied down before the crop begins to ripen, and vigorous growths that are likely to take support away from the fruit should be pinched out as the tying proceeds. Make additions to the mulchings as the roots appear on the surface, and seek to keep them there by watering at short intervals, once a week at least. Ventilate all houses early in the morning, allowing the temperature to rise gradually to 80°, keeping it at that to 85° through the day from sun heat, and reduce the ventilation gradually, closing on fine afternoons sufficiently early to allow of the sun raising the temperature to 85° or 90°.

Early-planted Trees.—When syringing can be resumed in the house from the first crop of fruit being gathered, the trees should have a thorough cleansing to free them from insects and dust, than which nothing is better than the garden engine. If scale has obtained a hold syringe with petroleum, a fluid ounce to three gallons of water, kept sharply stirred whilst being applied. Attend to stopping and tying, avoid laying in too much wood, and let ripening fruit have full exposure to light.

Cherry House.—In the case of trees that have only been slightly forced the fruit will now be ripe, forming a good succession to those that were ripe in May, and it will be necessary to see that the trees do not lack moisture at the roots. Water must be carefully kept from the fruit, but a fair amount of moisture should be maintained by damping the borders occasionally, and will not do any harm provided the house is subjected to free ventilation. In order to maintain a supply until those on walls come in, the house should be shaded whenever powerful sun prevails, and birds must be excluded by some netting fixed over the ventilators. The house should be fully ventilated at this season. Trees from which the fruit has been gathered should be syringed to dislodge dust or insects, and the house fumigated on two or three consecutive evenings if black aphides appear. See that there is no deficiency of moisture at the roots, as it is important the soil be kept thoroughly moist.

PINES.—At this season young growing stocks will need particular attention in order to keep the plants sturdy and vigorous, for which purpose it is advisable to divide them into two or three sections, as it is otherwise impracticable to do full justice to all the sorts under ordinary arrangements where the plants are mingled together, under which, for the sake of appearance, the stronger growers are placed at the back, and consequently best position, whilst the smaller are placed in the front or worst. Where practicable we advise the Queen plants to be grown by themselves, and Smooth Cayenne and Charlotte Rothschild together. The taller varieties, such as Black Jamaica, Enville, Black Prince, Montserrat, and Prince Albert, &c., should be placed together. Every care

should be taken to make the most of the sun heat, and, except for the sake of bottom heat, but little artificial warmth will now be required. The bottom heat should be kept steady at 90°, which is absolutely essential to keep Queens in satisfactory progress, and with a proper degree of heat at the roots an occasional low night temperature will not affect the growth prejudicially. A night temperature of 70° is suitable. Ventilate early in the morning or at 80°, and keep at 85° to 95° through the day from sun heat, closing at 85° to 90° with sun heat, and if the temperature rise 10° afterwards it will be more advantageous than otherwise. Keep the houses when closed well moistened, and sprinkle the plants two or three times a week according to the state of the weather. Water the plants regularly and copiously, but not until it is needed. It should be tepid, with the addition of 1 oz. of guano or soot to each gallon.

The night temperature in the fruiting department should be maintained at 75°. Admit air freely on all favourable occasions, as a close atmosphere is apt to increase the crowns out of all proportion to the fruit. Plants with fruit approaching ripening and close to the glass will be benefited by being slightly shaded for an hour or two at midday, and with the heat duly maintained a liberal course of ventilation will at this stage aid perfection in point of colour and quality. As soon as a fruit ripens it should be cut and removed to cooler quarters if it is to be kept.

PLANT HOUSES.

Clematis.—Plants of the early-flowering varieties that have been grown in pots and trained upon trellises should, if they have been gradually and carefully hardened, be placed outside. When first placed out they should be stood in some sheltered position, where they will be screened from cold winds until they can be plunged in the position they are intended to occupy during the summer. After these plants are placed outside they must not be neglected; the shoots as they extend should be kept tied round the trellis, and the plants well watered and liberally supplied with stimulants.

To save labour in watering it is a good plan to plunge their pots in ashes and mulch the surface of the soil with decayed manure. The large-flowering types in the conservatory will also do outside as soon as they have done flowering. Young plants growing on in the greenhouse should have their shoots as they extend trained to thin cord. These plants should be repotted if they need it, employing a compost of good loam, a seventh of manure, and a little sand.

Callas.—The stock intended for next autumn and winter flowering have now been hardened in a sheltered position outside, and should be planted out for the summer months. If necessary to increase the stock the plants may be divided as the work of planting proceeds. In planting, form a trench and incorporate a liberal quantity of decayed manure amongst the soil to be placed round their roots. When planting is completed the soil should be about 2 inches below the surface of the ground, so that liberal supplies of water can be given during dry weather, which is all the attention needed until they require lifting in September.

Choisya ternata.—Bushy young plants in 5-inch pots, or old plants that have been cut back and well broken into growth, should be hardened thoroughly by removing the lights from the frame in which they are growing, if not already hardened, for placing them outside. Select a sunny position, for they will do much better outside during summer and set their flower beds with greater freedom than if grown indoors. These plants require abundance of water. When the pots are full of roots liberal feeding may be resorted to.

THE BEE-KEEPER.

SEASONABLE NOTES ON BEES.

THE merry month of May, so far as the bee-keeper was concerned, did not merit its fair appellation. Rainless for the most part, and with the wind constantly in the east, hives were much retarded by the cold and even frosty nights and by the almost total absence of honey in the daytime. Dry weather generally gives much honey, and moist weather is productive of swarms; but cold parching weather, such as we have lately been experiencing, brings neither. In some very favoured spots where Mustard and early Beans are abundantly grown honey has doubtless been obtained in some quantity, and has already found its way to the Health Exhibition; but where fruit blossom is depended on as the principal source of income for the spring months the yield has been indeed very small.

The early days of the present month brought a change of wind. The genial westerly breezes and warmer nights at once caused a flow of honey, and several racks of sections were taken possession of by our bees. The long-hoped-for rain came at last on the 4th inst., and we looked forward to warm sunshine after it and quickly filled supers. But the sun god has been affronted, and refuses to smile again. Cloudy skies and very cold nights again prevail, and we expect to see our sections soon deserted and the bright hopes so lately formed as suddenly dispersed. The Sycamores and other honey-yielding trees and

shrubs will have shed their blossoms. It is a sad experience that bee-keepers soon learn, how quickly the wet and cold causes the various series of honey flowers to pass away. A few cold cloudy days and the blossoms expand and fall—gone for a whole season, without having contributed one drop of nectar to our imprisoned labourers. It is very disheartening to see the tens of thousands clustering for warmth; the labourers indeed very many, but the harvest nil. But just as the first warm breath from the south and the genial influence of returning sunshine will at once awaken into noisy rushing life the now listless myriads, even so, rise the bee-keeper's hopes, and again and again he looks forward to a busy joyous harvest.

Laurels have again been noticed by us to be one of the very best shrubs to plant for bees. Too many cannot be had near an apiary. Bees obtain much honey from them, principally collecting it from the axils of the leafstalks. It seems to exude from the plant and not to be a honeydew, the secretion of insects. The American Blackberries are now coming into flower, and, like the Raspberry, should weather permit, yield a bountiful supply. The fruit of these is delicious, and it is a pity that more are not grown by bee-keepers. They require deep rich soil, and cannot be too highly manured. Trained like the Raspberry to strained wires, or arched from stake to stake, they bear an abundance of bloom; and where bees have access to them the fruit is certain to be finer, every berry being perfectly fertilised. It is a pity that more attention is not paid by the owners of hives to planting such trees and shrubs near their bees as shall give occupation to their little favourites in the intervals between cloud and sunshine. We learn that Messrs. Sutton and Sons of Reading are about to ascertain the best kinds of seeds to sow for bees, to supply them in cheap packets. This will be a decided boon to bee-keepers. We last year mentioned Radishes as a fertile source of honey supply. If bee-keepers will allow a few plants to run to seed they will be surprised at the number of bees constantly working on the flowers. The golden Tom Thumb Wallflower has been much appreciated by our little workers, and but for the drought would have lasted much longer in blossom.

Stocks of bees should now be at their full strength, and supers should be put on in the nick of time. With abundance of bees and quantities of honey coming in, which must be the case when the rain has given a new stimulus to the honey-yielding flowers, supers will readily be entered. We are now obtaining sections from the body of the hive. Bees more readily commence drawing out the foundation there when the supply of honey is not great from without. These sections if not quickly finished below, should a glut of honey begin, will be moved to the racks above.

Swarms are common around us, but we are doing our best to prevent swarms this season, and so far we have succeeded. Our best time for increasing stocks is during the interval between the early yield and the Heather harvest. We wish to employ all our bees now in filling early supers. We then have time to build up stocks and swarms before the Heather is in full swing.

Several contributions have lately appeared in the Journal concerning the merits of black bees *versus* Ligurians. We have not been able to speak pointedly on this subject, because, although we have for many years had Ligurian blood in our apiary, we have never taken the trouble to keep it pure. Our Ligurians have soon become crossed with the black bees, if there is such a thing as a single stock of the old black race in existence. We much doubt it. Our own experience has been in favour of the hybrids. Our strongest stock at the present time is a crossed one, and there is every reason to hope that they will yield as heavy a surplus of honey as any stock we possess. We hope to be able to compare them late in the year with the seventeen other colonies in our possession. They are certainly rather more irritable than the ordinary English bees, although the pure Ligurians are much more docile. They are also without doubt more active than the natives, both earlier in the morning and later in the evening being abroad water-carrying. More fussy, perhaps some will say; Better nurses, say we. Their breeding propensities are certainly very great. By confining them to ten frames for brood-rearing, we, however, hope to utilise the powers of the vast army of foragers should opportunity offer.—P. H. P.

FERTILE WORKERS.

MR. JOHN HEWITT, Sheffield (page 433) draws my attention to his article in the *British Bee Journal* for June 15th, 1883, narrating his interesting experiment with black queen amongst Syrian workers, amongst the latter being a fertile worker that laid eggs contemporaneous with the queen. He then adds, "I believe I was the first to

discover or satisfactorily settle this interesting and valuable fact." While I am both interested and pleased to see Mr. Hewitt making and recording these accurate observations, I cannot corroborate the statement that he was the first to discover the phenomenon. The late Mr. T. W. Woodbury gave his evidence in this Journal of a case where eggs were laid in a hive that produced drones where a young unfertilised queen was. I am not sure, however, whether Mr. Woodbury attributed these eggs to fertile workers or to the queen. About that same time he had a Ligurian queen fertilised with a drone from a fertile worker, which I could fully endorse, as I had and knew of several parallel cases. Both before and after that date I had given the subject much attention as well as making many experiments. These proved how easy it was to raise at will fertile workers, and how difficult it was in some cases to introduce a queen to bees where they were while it was quite the reverse in others, so that my experiments do not warrant me to introduce a queen or expect it to be well received in any hive containing a fertile worker. In every case where a fertile worker is present to insure its deposition I join other strange bees to it, which in many cases I believe these stranger bees belonging to the queen to be introduced kill the fertile worker and make the bees passive and in a proper state to fraternise with the alien queen.

In consequence of ill health Mr. Hewitt's article in the *British Bee Journal* had escaped my notice until I read his remarks, page 433, when I turned up the pile since January, 1883. Many people were, and are still, sceptical as to the existence of fertile workers, and many hold erroneous opinions regarding their reproduction. One interesting case I had was that in a queenless hive I had inserted a piece of comb containing larvæ and eggs, as they ate out all eggs and larvæ except one, which was hatched on the tenth day after sealing. This was a Ligurian, and the only one in the hive which commenced laying the same day she was hatched. I watched her depositing eggs and receiving court from the other workers, showing her to many bee-keepers, and had her placed in an observatory hive; but an accident that befell her prevented me exhibiting her publicly at the Caledonian Apian Show in 1876.

With the view of proving whether the advice so often given was correct to shake the bees out some distance from its stand, and the bees would return, but if a fertile worker was present she would not. I tried this often, but the fertile worker always returned. In 1881 I had a Cyprian hive that raised upwards of 200 queens and many fertile workers. Many of these queens took shelter in adjoining hives which ejected as many as from six to a dozen; in others where only one had entered I found living along with a queen regnant at the end of two months. The fertile workers or rather in hives where fertile workers were present, the young queens were deposed, but with the many queens on hand I made up the loss, though I could not always depend on them being well received. What appeared to be successful in one case failed in another. Although I am satisfied that queens will at times be well received in hives containing a fertile worker, but not always, I advise where these pests are present, Do not risk the life of a valuable queen without taking precautionary measures.

While I do not doubt the accuracy of Mr. Hewitt's article and experiments, still there is a possibility of mistake. The yellow bees are so well distributed throughout Britain that it is difficult to say where a pure black bee is to be found, and it is because of these crosses being superior workers, and bee-keepers not knowing them to be other than pure blacks, that many believe the black bees are the best. The progeny of crossed queens are very interesting and various in their markings. I have had crosses with different races that not more than one in a hundred of the workers showed the markings of the drone's parentage, contrary to what is usually the case, where as a rule the one half partakes of the markings of queen and the other half that of the drone; yet, singular to say, I have seen the drone progeny of queens raised from the eggs of these crossed black queens that showed so little of the yellow blood extra prettily marked. This is where a half-breed queen might be mistaken for a pure one. Then some queens when they commence at first to lay, and for some time after, lay drone eggs only, and others have always a mixture of drones, while others produce great numbers of hermaphrodites; such queens are apt to mislead novices, and should be destroyed, as they never prove profitable. Persons wishing to repeat Mr. Hewitt's experiments should make sure that the queen chosen is not only of a distinct breed but that she is of undoubted purity.

Mr. Hewitt will, I trust, be satisfied from the foregoing that I have not used any of his articles for my own purposes, while I may further tell him that queens in workers cells were found by me thirty years ago, and if I remember aright I mentioned the facts stated in an essay written in 1882. It is by such experimenters as Mr. Hewitt that discoveries are made, and on such only can reliance be placed. I am proud to see him watching what he considers his rights and exposing imposition and what is wrong, but we know that

much claimed during the past ten years was made fully known in the pages of this Journal long ago.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUE RECEIVED.

Pringle & Horsford, Charlotte, Vermont, U.S.A.—List of Hardy North American Plants.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Wild Flowers (J. S.).—Besides the work you name you will find the "Handbook of British Plants" useful, which may be had from this office, price 3s. 6d., post free 3s. 8d.

Cattleya Mossiae (C. D.).—The variety is a very handsome one, and superior to many of the common forms in cultivation.

Grapes not Swelling (G.).—It is extremely improbable that the small berries will ever approach the size of the others, and the better plan would be to remove them if there are sufficient swelling freely to produce fairly full, if even rather small bunches. We cannot understand persons ceasing firing at any particular period of the year regardless of the state of the weather, except on compulsion, such as having no fuel. We scarcely think, however, that "cutting off the fire" was the sole cause of the Grapes not swelling. The chief cause we attribute to imperfect fertilisation, and the evil was increased by the subsequent chill that was imparted by a too low temperature.

Peach Leaves Blistered (W. H.).—The leaves you have sent are seriously attacked with the fungus *Ascomyces deformans*, which quite destroys the tissue, and occasionally almost destroys the trees. There is no simple remedy, and you cannot do better than remove all the worst leaves and hope for genial weather to promote free growth. The fungus is invariably the most prevalent during cold weather, when the trees received a chill and the sap is comparatively stagnant. Seriously blistered leaves are rarely seen under glass, and when the trees are effectively protected from cutting winds in spring. The subject is illustrated on page 519, vol. iv., third series, of this Journal, the issue of June 22nd, 1882.

Thrips on Vines (A Devon Gardener).—Fumigation intelligently performed will not injure Grapes when freely swelling after having been thinned. Tobacco smoke will destroy thrips, but not the eggs of the insects, and consequently the application must be repeated in the course of ten days, fumigating on two consecutive evenings in each case. If the first attacks are seen on a few leaves only, these may be quickly sponged, using any approved insecticide, and the thrips thus prevented invading the Vines. Nicotine soap, Fir-tree oil, or Gishurst compound applied through a spray-distributor will destroy thrips on the under-sides of the leaves, the upper surfaces, which are often attacked, not being easily reached by the solution from either a spray-distributor or syringe.

Indoor Fernery (A Constant Subscriber).—The wood that has been used for supporting the Ferns on the back wall of the fernery must have been very unsuitable for the purpose, or it would not have decayed so soon. Only the hardest wood should be used, the best of all being the hard, black, ebony-like roots of Oak trees. Stone is, of course, the most durable, and rustic pockets can be formed with cement, which are practically imperishable. Many walls are ornamentally covered with Ferns and Begonias by affixing very strong wire netting to studs, leaving a space of 2 or 3 inches between the wires and the wall. If rough soil is packed in, faced with moss, and the whole kept moist, various plants will luxuriate, and a very attractive surface be produced. If Oak is not obtainable Teak will be suitable.

Crocuses (Bodfare).—It is certainly wrong to "tear the grass from Crocuses while it is green, and pull up the bulbs with it." If such a practice is systematically pursued the Crocuses cannot fail to decrease and become weaker yearly. The grass should remain until it can be removed with the greatest ease without even breaking above the ground or disturbing the corms in the slightest. When quite matured it parts readily and naturally from the roots, and no more force is needed for withdrawing it than could be applied by a child a year old. If the withering leaves are not deemed unsightly they may remain until they can be cleared off with a fine-toothed rake.

The Shamrock (R. B.).—*Oxalis acetosella*, the Common Wood Sorrel, or Shamrock, is a native of the moist shady woods of this country, Europe, and

North America, and is one of the most elegant of wild flowers. It delights in retired shady woods, groves, and hedges, and flowers in April and May. It was called by the old herbalists Alleluja, and Cuckoo's Meat, because, as Gerard says, "when it springeth forth, the cuckoo singeth most; at which time also Alleluja was wont to be sung in our churches." But Alleluja is merely a corruption of the Calabrian name Juliola. The whole plant has a grateful acid taste, much more so than the common Sorrel, and is on that account used in salads and in saucers. In Lapland it is so plentiful that Linnaeus says the inhabitants of that country take scarcely any other vegetable food than Sorrel and Angelica. The expressed juice of the plant is employed to remove spots and iron-moulds from linen, and this it does by the great quantity of binxalate of potassa which it contains. Twenty pounds of the fresh leaves have been found to yield 6 lbs. of juice, from which 2 ozs. 2 drachms, and 1 scruple of salt, besides 2 ozs. and 6 drachms of an impure saline mass are obtained, and is sold under the name of salt of sorrel and essential salt of lemons. It is prepared in Switzerland and Germany from different species of *Oxalis* and *Rumex*.

Cutting-down Yew Hedge (G. V.).—We once had a similar hedge to deal with, and cut it partially down at first, but, as we anticipated, this did not answer. We then cut off the branches close to the stems of the trees, for stunted trees they really were, removed the old soil from the roots, thoroughly saturated the dry ground, added fresh soil, with a surfacing of rich manure. Fresh growths were then produced from the stems and a healthy hedge formed. Whether your hedge is too much exhausted for renovation we have no means of knowing, but we are convinced it will not be improved by the "half-shortening" you suggest as the alternate plan.

Pruning Plum Trees (Idem).—Plums do not bear on young wood with the same freedom as Peaches do, nevertheless they will bear on short-jointed well-matured shoots of the previous year's growth. It is very easy to err, however, in securing too many of these to the wall, thus overcrowding the foliage, which is a sure way to prevent the formation of blossom buds. The trees bear admirably on spurs and on hard stubby shoots from 4 to 6 inches in length, that never fail to form on our trees when the stronger growths are pinched. There is no objection whatever to securing some of the young growths to the wall when there is ample room between the main branches for the leaves to develop without overlapping those on the spurs. Subject to the careful avoidance of overcrowding, the combination of young wood and spurs may with safety be adopted, as this system properly carried out is productive of good crops of fruit. The precise method to adopt, however, depends on the condition of the trees. We have trees in the most satisfactory bearing state that are managed on the spur system exclusively, and others, with which we find it advantageous to lay in some young wood annually, removing unfruitful portions at the winter pruning; in fact, many are removed in the summer, but an experienced eye is requisite for determining which to remove and which retain.

Various (Cambridge).—We cannot understand your failure to obtain seed of the Virginian Tobacco from any of the firms you name, except on the assumption that you did not apply soon enough. We find it in the catalogue of Messrs. Carter & Co., and also under the exact names we gave in that of Messrs. Veitch & Sons of Chelsea, and we shall be surprised if it is not procurable from the principal seed firm in the town near which you reside. We are not able to state whence you can obtain plants, as we know of no nurserymen who raise them for sale. We have, however, written to a gardener who grows Tobacco for fumigating, and if he has any surplus plants he will send you a few. This is all we can do in the matter. It is, for obvious reasons, contrary to our established rule to recommend the seeds of any particular dealer as the "best;" and as you wish to have the "very best strain" that is procurable of the flowers you name, your only certain course of succeeding is to procure a packet of seed from each of those dealers who offer special strains, select the best flowers from the whole of them, and from those save seed. By no other means can you secure the "very best strain," as flowers equally good are obtained from the seed of the different growers who pay special attention in the selection of varieties for producing it. We will endeavour to procure you the information you need for your carpet bed. You have deferred your request, however, so long as to render it impossible for us to state this week whether we should succeed or not in our desire to assist you in the matter.

Culture of Abutilons (South Wilts).—Your plants have either been kept too cold, or they have not had the support they need for keeping them healthy. Some time ago a successful cultivator of these plants wrote as follows:—To grow Abutilons for producing flowers in large quantities they should be planted out against a pillar, rafter, or where they can cover a wall. Standards grown in large pots or tubs are also very effective in large conservatories. These plants flower almost the whole year if properly and liberally treated. When plants have attained a fair size in either pots or tubs they require liberal feeding and rich top-dressings frequently to keep them healthy, otherwise the foliage turns sickly, the wood becomes hard, and the flowers are few in number. Plants can also be flowered well in 4 and 5-inch pots. They thrive well under greenhouse and cool-frame treatment during the summer months, but will not flourish so well in the greenhouse during winter as in a house that is kept a little warmer. They do fairly well in conservatories where the temperature is not allowed to fall below 45° by night; but better, and continue to grow and flower with greater freedom, in an intermediate house where the temperature is maintained between 50° and 55°, according to external conditions. To maintain a succession during winter and spring two batches should be propagated—one in July, and the other towards the end of August or early in September. It is useless to propagate for this purpose earlier, as the plants only become tall. The cuttings should be inserted in thumb pots, as every one will root if placed in close handlights in Cucumber and Melon houses, and kept shaded from strong sun. As soon as the young plants are rooted they must be gradually accustomed to cool treatment; in fact, we generally have ours in a cold frame by the time they are ready for 4 or 5-inch pots, and the only shift the plants get after they have filled the small pots in which they are rooted. This batch we grow in cold frames as long as the weather will allow us to do so without checking the plants. Growth from the time of rooting is slow, and the plants are sturdy and strong with fine foliage down to the rims of the pots. We give preference to good strong cuttings, such

as can be obtained by removing the ends of leading shoots, and then the plants are well furnished from the commencement. They seldom lose their foliage in the operation of rooting if judiciously treated. While growing Abutilons must not suffer by the want of water, and when the pots are full of roots liberal feeding must be resorted to. Stimulants should be given every time watering is necessary, by which means the plants are kept in a healthy vigorous condition. Good loam, to which is added one-seventh of manure, with sufficient sand to keep the whole porous, will grow them well. If this reply does not meet your requirements please write again, and describe the conditions under which your plants are grown.

Cucumbers Diseased (G. B.).—If your plants are affected with what is known as the "fruit form" of the "disease," we fear you will find it difficult to extirpate. Mr. Taylor succeeded in banishing it from Longleat by what he termed "isolation." Plants were raised and grown in an old house quite away from those in which the disease was rife; the attendant had his separate waterpots, &c.; he procured water from a different source, and had nothing to do with the houses where the diseased plants were. The first isolated stock of plants did very well, and we started another lot for the summer on a dung bed. This was also kept isolated from the Cucumber house proper with the same result. The house in which the diseased plants had been growing was fumigated with sulphur, every part that could be reached was scalded with boiling water, the walls were limewashed, the woodwork painted, and the house remained clear of Cucumbers for four or five months, during which time no disease was seen on the place. The result was plants in full bearing in the most perfect condition." Another correspondent, Mr. T. Weaver, wrote on this subject last year. "I had some experience with this much-dreaded pest a few years ago in a garden where Cucumbers were in great demand. It was then August, and every probable remedy had been tried that could be thought of—viz., new soils and fresh seed obtained from a source where there was no Cucumber disease; but the results were that as soon as the first fruits were seen the disease appeared. Cucumbers were, however, wanted winter and summer, so after trying all remedies by day we determined to begin by night. Fumigating with tobacco paper three nights in succession was tried, the atmosphere being kept drier and the temperature higher. After three or four nights fumigating was again tried. This treatment was carried on for about three weeks. The plants were then carefully examined, and all spotted leaves and gummed fruits removed, a top-dressing of fresh soil being applied. The result was that the plants started growing freely, and produced a very fair crop of fruit for Christmas and on till February, quite free from spot or gum. After that I always kept a sharp look-out for the first spot, and if any was seen the fumigator was placed in the house two hours after dark. The two following seasons Cucumbers were cut by hundreds without a spot. I feel sure if your correspondent will try the above cure next season he will not suffer from this troublesome pest. I may add that I have not seen any traces of it for over three years." The "correspondent" alluded to was Mr. Harding of Orton Hall, who had to battle with the disease in its most inveterate form. He found that raising the temperature of the house 10° had a beneficial effect. We believe his plants are now clean, and we shall be glad if he will state to what he mainly attributes the banishment of the disease.

Names of Insects (R. C., Sevenoaks).—Your No. 1 is a beetle, one of those called rove or cocktail beetles, *Staphylinus fuscus*. In habit they are predatory, and remarkable for their very short wing cases; though possessing wings, they rarely fly. No. 2 is one of the tiger beetles, *Cincindila campestris*. These are insects of rapid flight by day; the larvæ or grubs excavate holes in sandy places, into which they drag and devour such smaller insects as they can secure. The other specimen, No. 3, is the larva, seemingly, of *Agriotes linearis*, another beetle, and a species which is occasionally found about gardens; the larva is a subterranean feeder, but does not cause any serious damage to plants. Such is, however, caused by the wireworms of the genus *Elatér*; and the insect, of which you add a description, is probably one of these, though we cannot speak positively.

Names of Plants (G. R. and J. S. B.).—The Whitebeam, *Pyrus Aria* (J. W., Essex).—1, *Sedum carneum variegatum*; 2, *Diplacus glutinosus*. Both are greenhouse plants, but the former will grow well out of doors in the summer months. (L. W.).—The Laburnum is *Cytisus Adami*, concerning which some information was given last week. The other is *Mespilus Smithi*, or Smith's Medlar. The specimen sent this time was a much better one than the last, and we are in consequence enabled to give you the correct name. (J. J., Lancashire).—1, *Pescatorea bella*; 2, *Dendrobium crassinode*; 3, *Oncidium carthaginense*. (G. W. C.).—The white-flowered Orchid is *Dendrobium mesochlorum*. (W. J., Doncaster).—1, *Linaria Cymbalaria*; 2, *Corydalis lutea*; 3, *Cornus mascula variegata*; 4, *Asphodelus luteus*; 5, *Saxifraga granulata flore-pleno*. (R. A. P.).—*Negundo fraxinifolium*.

Honeycomb in Sections (J. S.).—From the fact of your queens being two years old it is almost impossible to prevent swarming. Young queens with large breeding space are the only sure means to prevent swarming. If your straw hives have less breeding space than from 1600 to 1800 superficial inches double side comb they are too small, and should be eked to that size, then the sections placed as supers, tiered one above another in crates, keeping the bees constantly at work by adding an additional tier as the previous one is well begun. If the frame hives are too small place a crate filled with frames above the stock. The outer frames of this crate should be for sections, but you would find more satisfaction and profit were you to swarm the hive (as swarms always work more eagerly than non-swarmers), and double or join two swarms together, then when two-thirds filled with comb add supers or sections. We shall shortly publish notes that will be useful to you, and apiarian articles will appear from time to time equal in interest and possessing at least the same practical value as any that have appeared in the past. You will not find anything of the same nature in the other paper to which you allude. We are obliged by your letter.

COVENT GARDEN MARKET.—JUNE 11TH.

ARABLE AND PASTURE FARMING.

(Continued from page 458.)

THE best pasture lands are frequently much depreciated when occupied by inexperienced tenants, or even by home farmers who are employed in districts with which they are totally unacquainted. This is especially the case in such large enclosures as are met with in Buckinghamshire, and more particularly in the Vale of Aylesbury, where many valuable pastures contain large acreages, and the soil consequently varies much in quality as well as the grass produced thereon. In consequence these hillocks of various dimensions, although they are necessarily fed off by fattening bullocks, contribute but little towards fattening the stock. As they cannot be separated, however, it is of the highest importance that they should be raised in value as nearly as possible equal to that of the best portions. This will be best done with applications of earth and dung composts laid out in alternate seasons with 4 or 5 cwt. per acre of the best bone superphosphate, the latter being applied in February of the year succeeding that of the compost manure, and thus continued alternately until the desired improvement is secured. We are now referring to those best pastures whereon the cattle never receive cake or artificial feeding mixtures of any kind, and yet become prime beef by summer feeding. Even portions of such fields we have noticed that the Clovers have entirely disappeared, probably from sheep feeding combined with oxen. It is sometimes conjectured that portions of these pastures are too wet, which destroys the Clover; but let it be remembered there is one infallible rule to be observed, that in case no rushes appear it is certain that the land is not too wet for growing land; and were it drained it would cause irreparable injury, for we have seen strong land pastures after being drained reduced more than half their original value, as in the summer season the land would become open, the pastures would then for months prove absolutely sterile. Again, portions of such land are often injured by hassocks of coarse grass or the bunch rushes. In either case the remedy is to cut up with the turf-cutter and burn them into ashes, and then sow Cocksfoot Grass and White Clover seeds, spreading the ashes and compost manures over the surface. This will reclaim any such land which has deteriorated through neglect. These improvements are essential, because we are now dealing with grass land which lets at a high rental and should be made available for bullock-fattening without artificial food, because it is this alone which can justify a high rental. On such land the labour question ought to be reduced to the lowest possible amount; an instance and illustration of which we can give, as the late Mr. James Crew of Wincanton, Somerset, bought two North Devon bullocks just beneath the butcher's quality at the Christmas market at Salisbury for £32 each, placed them in his feeding pastures in the Vale of Wincanton, and by grazing on the land in summer and consuming hay in the winter the produce of the adjoining pasture had only a hovel or shed to lie in, but without receiving any other food than the produce of the pasture either in grass or hay, were fattened and sold at the next year's Christmas market at Salisbury

for £64 each. This is an instance of the value of grazing cattle well worth the attention of every farmer who has the best grazing land in his occupation, for it illustrates most forcibly a leading point in grazing, where the produce of arable land or the use of artificial food is entirely absent, and with the least cost in labour expended during the time of fattening.

In certain districts of the kingdom where the land is capable of fattening an ox without additional food other than grass or hay, it must be accepted as the most valuable that can be found. On such soils and situations where the pastures are so productive it may be safely pronounced that no arable land in the immediate district and of similar soil can be cultivated with any comparison in the profits to be derived therefrom. These facts are patent to every experienced farmer. Such land under cultivation may with the greatest safety be laid into pasture and ignore cultivation entirely, especially under the influence and the advantage to be derived through the new system of using the best pasture grasses as practised by Mr. Faunce de Laune, and to which we have recently referred in this Journal, and shown therein that there need be not only no failure, but a good pasture the first year, and ever afterwards if properly managed. One of the most important points, however, must not be overlooked—that is, obtaining cattle suitable for grazing these valuable pastures. The old system was to purchase four-year-old cattle in good store condition before turning them out to graze. It is, however, now very difficult to obtain four-year-old bullocks except those which are called worked oxen, and these are only available in small numbers.

We have before us an article headed "Young Beef," by a member of the Smithfield Club, Leeds, in which it is stated that the rapidity of growth during the fattening process diminishes year by year with age. During six successive years it was 2.58, 2.05, 1.96, 1.57, 1.37, and 0.89 lbs. successively per diem—a fact entirely corroborative of our argument. This is an excellent practical illustration of our own observation and long experience in this matter, and we can see no reason why it should not be applied in the case of grazing the best pastures instead of purchasing only oxen of full age, for it will of course prove the best method of promoting and securing commercial profits. It, however, involves either a breeding establishment or otherwise the rearing of calves selected in the cheese-making districts, and reared upon the farm which should necessarily contain some arable land for the production of roots, straw, &c., for food and accommodation for the young animals in the winter months. The foundation would then be laid for their future grazing up to two years or thirty months old, from which time they would be grazing for one summer and going to market as beef at about three years of age. In this way we think it should be the system for adoption in the absence of a supply equal to the demand of store animals for grazing.

Turning our attention to the arable lands of districts to which we have been referring, we readily admit that it would be difficult to find arable land turned to so good an account commercially as the best pasture may be, although the soil and climate may be equal in fertility. This appears to be the case at present with so large a number of arable farms which are untenanted, indicating with the greatest security the benefit of laying down such land to permanent pasture under the new method of selection of grass seeds, and of seeding in a Wheat crop if possible. The same indications which would direct the home farmer in laying down certain soils to permanent pasture, point out to him not only the best soils for grazing land, but also decide the question of any other soils and variations of climate by noting the pastures which have been from time immemorial laid in grass. They will also show to what extent the mixed soils prevail, and the former management having consisted of dairy farming and corn-growing combined it will be seen what changes can be made with advantage. We are now alluding to a system of dairy farming either for the production of cheese or butter, although it will still be a matter for serious consideration that some portion of arable is a necessity; still this should also be viewed and made a point of the extent to which arable may be combined in the occupation. We may also refer to some farms, although containing a large portion of arable, whether it may not be an advantageous system in the absence of sheep to keep a suckling dairy, and yet be enabled to make profits equal to that of butter and cheese-making without the labour, knowledge, establishment, &c., required in the manufacture of these articles. Unless they are manufactured under the practical and scientific knowledge which now prevails, the fattening by suckling of calves for veal would be the most profitable, the most simple, the less risk, and the actual retention of the cows in profit for the longest periods, as well as the least labour in management, especially when we consider the high price of veal and great requirements of the present period, and at the same time bearing in mind that choice veal of the best size and quality is now, and is likely to be in the future, like choice young lambs, the principal stock productions which do not meet with a foreign competition. In alluding to the advantages of a suckling dairy, it is frequently adopted in outlying districts farthest from the markets or town, and railway

stations, which include some extra charges for the constant delivery of produce like butter and cheese, and there is also a sure and ready money market for veal not always to be obtained for butter, cheese, or milk.

The management and cropping of the arable land connected with grass land in dairy farming is a very important matter, because the actual growth of green food in summer supplementary to the grazing of the cows does, when given at the stalls, to some extent render artificial feeding stuffs like cake unnecessary, excepting in the case of poor pastures, when it would prove beneficial in two ways—by an increased production of milk, and increased growth of grass on the pastures. In the observations we intend to make with reference to the capacity of either arable or pasture land to yield full commercial advantages, we shall endeavour to lay before the home farmer, and incidentally before the occupying farmers of the kingdom, not only in reference to those soils which are most likely to succeed best under tillage or in grass, but the methods by which the best results are most likely to be obtained. Let us take, for instance, the customary mode of an occasional fallow, which probably by the great majority of farmers and landowners is considered a proceeding essential to success in the cultivation of any arable land; and so it is if the land is foul with couch and weeds, but not otherwise, for in our own experience we farmed lands without making a fallow for more than twenty years in succession, and yet the land was quite clean and yielding full crops of every kind of crop suitable to the soil.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are still engaged in the preparation of the land for root crops; in the northern counties and Scotland, however, the Swede seed has been drilled for some time past. This is at any rate the best time for that work in the midlands, southern, home, eastern, and western counties. If dry weather prevails the Turnip flea or beetle will probably destroy many of the young plants as soon as they show the first leaves; but we have known many farmers frequently attribute this to various causes, such as bad seed or not vegetating from dryness of the soil. It must, however, be remembered that the brown grub, which in its infant state travels at night, eats the first leaves which attempt to show on the surface, hence the unreal inferences often drawn from the non-appearance of the young plants. These grubs are the same sort which when more fully grown often eat off the roots of the Turnip plants as well as those of Mangolds, Carrots, and Cabbages after being hoed out. Clover crops and Sainfoin, as well as mixtures of other grasses for the alternate husbandry, should now be cut just as the blossoms begin to appear, but especially those mixtures of Clovers which were intended to produce a second growth or even a third on good land in a high state of cultivation, more particularly where the layer had been manured with yard or town dung in the previous winter or early spring months, as this is found to accelerate any after-growth, whether for hay, sheep-feeding, or seeding. We, however, strongly object to the practice of feeding the after-growth of Clovers with sheep in all cases when the leas are intended for Wheat. We have frequently seen the best Wheat grown where the Clover as an after-crop has been saved for hay, and even saved for seed, as the lea proves a more valuable preparation for Wheat in consequence of the increased weight and substance of the Clover roots. In reference to tillage operations we especially recommend that in the seeding, and indeed preparation for late Turnips, Rape, Thousand-headed Kale, that a dry season should be provided for, because in case the season later on should prove the reverse, yet the preparation will be favourable, for frequently in dry seasons we may obtain rain enough to vegetate the small seeds of various kinds in the event of the land being in a fine and pulverised state to receive it, yet when tillage work is delayed by waiting for rain before breaking the clods we may not obtain a sufficient rainfall to vegetate small seeds, and the crop may be lost in such a case. Although we have been engaged in tillage and cropping of the land ever since 1827, yet we do not recollect a cycle of nine seasons all of which were adverse to the Wheat crop; but one singular coincidence we remember is that great and abundant Wheat crop have occurred in the following years—namely, 1834, 1844, 1854, 1864, and 1874, notwithstanding we have secured in other years abundant Wheat crops, especially in 1835, 1836, also in 1868, 1870; and if we should obtain a fine Wheat crop in the coming harvest it will again extend the singularity of such a succession of abundantly yielding crops. There has been, however, during our experience only one year—viz., in 1868, when all the cereal crops were abundant, for it must be remembered that on all other periods when an abundant Wheat crop has been obtained the season has proved too dry for Lent corn, pulse, and hay crops, as well as root crops. On the other hand the nine past seasons have been singularly favourable for nearly all kinds of produce on the hill farms and eastern counties produce, except Wheat. The late moist seasons have been greatly in favour of the dairy farmers as well as graziers, and the breeding flocks of sheep on the chalk and limestone hill districts of various counties.

Hand Labour.—Men will now be fully employed in hoeing the various root crops as they come to hand, also mowing and removing the crops of Clover, Sainfoin, Trifolium, and water meadow grasses, either for hay or ensilage. On some farms both modes of preservation of green fodders will be adopted, and where the produce will be required for sale

haymaking will still prevail if the season continues dry, and to the great majority of farmers the ensilage question will not be available; but silos should be available, especially in dairying districts, for the obtaining of ensilage in the winter and spring months will enable the butter-making dairies to turn out a valuable record of butter. Still we must ask those men who have been in the habit of allowing their cows to go dry for three or four months in the autumn and winter to give up their customs and prejudices, in order to avail themselves of the commercial benefits to be derived from the use of ensilage, or in fact, upon any farm where the cows can be fed with roots, bran, hay, maize, &c., instead of their cows being out of profit when their produce is of the most value.

Live Stock.—As calves can now be reared in a healthy and growing state without milk at small cost, it is important that it should be done, so that not only the farmer should raise calves enough to maintain the numbers of cows in the herd, but also be enabled to bring some forward to meet the demand caused by a diminished stock of horned cattle in the country, as shown by statistical accounts and records. Events in America, the news of which arrived last week—namely, that the manufacture of oleomargarine has been forbidden by the Legislature, ought to stimulate the endeavours of dairymen to exertions in their own interest, because if oleomargarine is not to be obtained in America, as also in this and other countries; for American butterine oil, the produce of America, has found its way not only into some dairies rented in this country, but also into continental districts which have supplied us with butter to a large extent, such as it was; yet it met with customers amongst a certain class, who could not afford to buy the best made fresh butter of this country. These facts ought to encourage the dairy farmers of this country to renewed exertions in various ways, but especially to prevent their cows going dry until they spring to calve again. The flocks of sheep on the hill farms, where a sufficiency of water can be obtained, ought to be doing well, although the weather has been rather dry lately; for it has been said in reference to this matter that the grass has most value for feeding in dry weather. The bullocks now being fed for the butcher, whether in the boxes or grazing on the pastures, should be pushed forward by good feeding with cake and maize meal, given mixed with some cut Mangold in their boxes; but many cases will occur on the pastures or park lands where the land is not of first-rate character, when the cattle should receive the same food in troughs or skeps on the grass land in order that the animals may be ready by July or August, the best time for selling summer beef, particularly of young cattle of light weights, as these furnish joints of moderate size well adapted for consumers in the summer months.

OUR LETTER BOX.

White Scour in Young Calves (Old Subscriber).—This, though frequently fatal, may be cured if taken in time. First, do not allow the calf to visit the cow as before, but wean it altogether, feeding with the best known milk substitutes, of which there are many now offered, such as Simpson's Ayre's calf meal, &c. The immediate remedy which is necessary should be:—Take a teaspoonful of laudanum mixed with a little warm oat-meal gruel, and a teaspoonful of prepared chalk, to be repeated every four hours until the diarrhoea ceases.

The Cultivation of Kohl Rabi (J. S.).—This may be successfully grown upon the same plan as adopted for Cabbages—that is, raised in beds, then planted out either on the stretch or on the flat, placing the dung in the centre of the stretch, or otherwise laying it out and raking it into every third furrow, and plant along the furrows directly over the manure. The seed, however, may be drilled and then horse-hoed between the rows, and the plants hand-hoed to the required distance apart. Full information on the cultivation of Kohl Rabi was given in the number of this Journal dated March 18th, 1880.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 1st.—Fine, and fairly bright.
- 2nd.—Pleasant, but generally dull.
- 3rd.—Rather brighter, but spots of rain.
- 4th.—Dull, rain in afternoon and evening.
- 5th.—Dull morning; very heavy rain began at 2.30 P.M., half an inch fell in an hour and a quarter; the heaviest part of the rain was over by 6 P.M., but the fall continued till midnight.
- 6th.—Rain nearly incessant from 6 A.M. to 6 P.M., then fair.
- 7th.—Rain from 1 to 8 A.M., then fair, except a few drops.

Temperature on the whole near the average, but occasionally much below it. Very heavy rain on 5th and 6th, just one-tenth of the average quantity for a whole year falling on those two days.—G. J. SYMONS.

THOUGHTS ON CURRENT TOPICS.

THINKING backwards is a process by no means difficult when exercised in connection with the contents of a book or journal. It simply means starting at the end at which it is usual to finish, and concluding with the page at which it is usual to commence. I think I have heard it said that some of the most able "reviewers" adopt that system; and as the practice of "apeing our superiors" is not yet obsolete, I shall not be out of fashion at any rate by attempting to proceed on the same lines.

I FIRST pause over a little unpretending paragraph next the bees, having reference to a not too widely known greenhouse plant—*Choysia ternata*. This plant is often seen long, lanky, and miserable because kept under glass always and not sufficiently pruned. The writer of the few lines in question hits the nail on the head when he refers to cutting back the plants and eventually placing them in the open air, as they "do much better outside than in during the summer." This is very true. The best examples of culture I have seen were planted out in prepared soil on a sheltered border, attentively watered, and taken up and potted in early autumn. I have often thought it is not possible to produce such dwarf bushy plants with bright foliage, and every shoot terminating with a truss of pure white flowers, by any other method of culture. At any rate, it is a mistake to keep the plants under glass and not cut them down, for they can no more be well produced in that way than can show *Pelargoniums*. Persons intending growing this useful plant will do well to think over the little paragraph above referred to.

TURNING backwards to the next page, a few lines on selecting early the wood of Peach trees and disposing it thinly contains in small compass abundant "food for thought." Of all the mistaken practices that are indulged in where they ought never to be seen, that of crowding-in shoots in summer to afford employment for cutting them out in winter is one of the greatest. If the thousand-and-one individuals would "think" a little more about the work in which they are engaged, instead of following a mere imitative rule-and-thumb practice of somebody else as thoughtless as themselves, they would not so frequently have to deplore the failure of Peach crops. Let the maxim in the paragraph on page 473 be "learned by heart" by every young gardener—"A fruit tree is cultivated solely for its fruit, and therefore no shoot or branch should be retained upon it, or rather be allowed to grow at all, if it does not in some way contribute to the desired end." Repeat that until it is mastered; think about it until its full significance is comprehended, and a lesson will be learned in fruit-culture that may stand the pupil in good stead, and perhaps may make him famous in his generation.

SUMMER-PRUNING Currants is alluded to in the next No. 208.—VOL. VIII., THIRD SERIES.

sentence. It is a good practice when done in time, but let it be remembered that pinching the shoots to two or three leaves *now*, as advised, is very different to allowing the breastwood to grow until the fruit is about ripening and cut off the shoots to two or three leaves *then*, because those two or three leaves suddenly exposed will shrivel at once if the weather be hot, and the bulk of the fruit will shrivel too, as many bushels did once upon a time when a certain young cultivator, by want of thought, "let daylight in" with a vengeance and roasted the crop. Following advice a fortnight or three weeks after date often ends disastrously; the adviser is then, of course, blamed, the real blunderer never thinking for a moment that any fault can attach to him; but it is "all along a-reading that there paper."

"M. M." is on safe ground in recommending greenhouse *Rhododendrons*. There are few that are not beautiful; but one is named that does not often receive honourable mention—namely, *Rhododendron fragrantissimum*. This is not only charming by the purity of its flowers, but its fragrance is delicious, resembling Honeysuckle intensified, and hence ranking amongst the sweetest of conservatory plants in spring. I thought when I read about these plants only "15 inches high, bearing many fine trusses of splendid blooms," that I should like to have seen them, as I did not know that this too-much-overlooked species or variety, whichever it is, would flower so freely in such a dwarf state. How does "M. M." propagate them? on what stock are they grafted? and will someone state the origin of this the sweetest of all *Rhododendrons*? The particulars requested would, I think, be acceptable to many readers of the Journal.

AND now I come to a series of paragraphs of a kind that periodically puzzle me. I try to think them over, but really do not know what to think about them. The labours of the Scientific Committee of the Royal Horticultural Society must presumably be very interesting to themselves, and the records instructive to persons of keen perceptive faculties. I try to picture in my mind the various abnormalities, malformations, and vegetable quixoticisms provided, and fancy I see the learned scrutineers at work with their eye-glasses, and try to imagine the erudite remarks as the subjects are passed on to somebody for "examination and report." The exams are made, no doubt, and the "reports" duly registered. What a bulk of wisdom must be pigeon-holed somewhere for the use of—well, I think it must be for the members of the Scientific Committee. I cannot drive my thoughts beyond that at present.

THE accounts of the Fruit and Floral Committees are more intelligible, and valuable as records of the progress that is being made in the horticultural world; valuable also as stamping with authority those which are really good amongst the bewildering numbers of claimants to popular favour. There may occasionally be good things passed unhonoured at these meetings, but it is something to feel that it is exceedingly rare for anything that is bad to be granted a certificate. In the fruit and vegetable departments very few mistakes indeed have been made, and I think the Committees merit what they so often accord to others—a vote of thanks.

PYRETHRUMS seem to have been in large force at the last meeting. The report says they were "superbly shown," and I think some of them are "superbly" named. Is Langport classical ground, at least that portion on which the single varieties are grown? for the doubles, I perceive, have earthly names, and rememberable; but how such outlandish names as Abacena, Abdarites, Abarinion, Acacisius, Babysra, and Nisbola can be considered appropriate for these simple and pretty border flowers passes my comprehension. They will never rest in the memories and fit comfortably the mouths of the majority, and hence can scarcely advance the

No. 1864.—VOL. LXX., OLD SERIES.

popularity of the truly English flowers on which they are inflicted. They must be very learned at Langport.

At last we have something like a solution of the conflict of opinion as to the distinctness of *Lilium Harrisii* from *L. longiflorum*. Some persons maintain their identity; others as strongly believe in their dissimilarity. If, as appears not unlikely, the bulbs have "got mixed," there is no wonder that confusion should have arisen, and in such case the disputants are in the happy position of all being right. The true Bermuda Lily is very beautiful, and I think dissimilar from and superior to both *L. longiflorum* and its variety *eximium*.

THE subject of pruning Gooseberries is incidentally alluded to in a note on page 465, in which it is stated examples of pruning and non-pruning may be seen in the neighbourhood of the metropolis, and in nearly every case the unpruned bushes have the best of the crop. Possibly similar examples may be seen elsewhere, such as neglected bushes of cottagers being laden with fruit, and the scientifically pruned trees in the squire's garden practically barren. I was taught to prune severely and leave the centres of the trees sufficiently open to place my hat in. For years I stupidly and thoughtlessly carried out the system, and was often annoyed in not being able to gather a hatful of berries. For ten years (1864 to 1874) that method was adopted with never a full crop of fruit weighing down the branches; for ten years (1874 to 1884) not a tenth part of the time previously occupied has been spent in pruning, and certainly ten times the weight of Gooseberries were gathered. This year is no exception; bushes slightly pruned are bearing heavily, while over the wall in the next garden, where close pruning is the order of the day, there are no Gooseberries. Next year the trees in that garden are to be differently treated; every alternate row only is to be pruned, and I have bet the gardener a new hat that those let alone will bear one-third greater weight of fruit than the others. I think I shall win.

MR. MUIR'S notes on Celery are suggestive. A good deal of the bolting of Celery results from the bad practice of leaving the plants in nursery beds too long, and permitting them to become 9 or 10 inches high before being planted in the trenches. If hot weather follows it is almost impossible to keep such plants steadily moving, except backwards, and then flower spikes almost inevitably form. When Celery is grown by the acre for market no such practice is adopted, nor are deep trenches made and filled with an extravagant quantity of manure. Sufficient to start the plants and an abundance of liquid food afterwards produces good Celery. The driblet system of earthing is attended with one danger—the extreme liability of the roots getting dry when buried under 6 or 8 inches of soil, and this alone has been the cause of thousands of Celery plants bolting. The longer the earth is packed round the stems, too, the more are they eaten where grubs abound. It is very easy to err by commencing earthing too soon, but a thick mulching of manure or short grass from lawns is valuable in keeping the roots moist, and it lessens the necessity of such frequent waterings.

THE subject of mulching is admirably treated by Mr. Iggulden, whose remarks on page 459 are as sound as they are opportune. Daily sprinkling flower beds with cold water is pernicious, as the consequent evaporation extracts the heat from the soil as fast as it is imparted by the sun, and the roots perish while the leaves scorch. That, I think, is the cause of so many plants refusing to grow that are half watered daily in hot weather. They may be sprinkled until they positively starve to death. One thorough weekly watering, giving sufficient to pass quite to the subsoil, and mulching the surface to prevent evaporation, and consequently retaining both heat and moisture, is infinitely more

potent in promoting the growth of plants than daily sprinklings that seem so fashionable. There are so many extremists in the world that the expression of opinion in favour of shallow *versus* deep cultivation of vegetables may not prove of the greatest benefit. The surface-scratchers will have an excuse to go on scratching, and if their crops fail in dry weather they will be fortified with an authority. I think a revolutionary innovation of that nature should not be in the form of an interpolatory sentence. The subject should be treated more fully or let alone, or the meaning of the innovator will not be rightly understood by all.

I THINK that is all I have to say at present, except to observe that I cannot undertake to "think aloud" every week, as I have been invited to do by the writers of some letters that have been forwarded to me by the Editor.—A THINKER.

ESPALIERS.

WHY do I recommend on page 437 the converting of horizontal espaliers into palmette verriers? Because, as is clearly stated in that article, "its inherent weakness of form invariably led to premature barrenness and decay in the lower branches." That this statement is borne out by facts there can be no question. In many an old garden have I seen espaliers with the lower branches in various stages of decay while the top was still in full vigour, and I have lived long enough to see a considerable number of espaliers planted in the best of soils for fruit culture (a deep rich loam, brought into fruiting under careful and skilful culture, yielding four bushels of fruit to a tree; fruit, too, so fine that I have a note of a Gloria Mundi Apple picked off one of them weighing 23 ozs.) reaching the stage of barrenness, debility, decay, followed by the equally inevitable cutting down, grubbing, and replacing with young trees. It will therefore be evident that I have ample reason for not saying "Agreed" to "A Thinker's" inference that I should be disposed to leave such trees alone.

When I sat down to write the paper on espalier Apple trees I had no intention of making the drawing printed with it, and did so simply to make the matter clear, just as one is apt to make a hasty sketch in a letter to illustrate one's meaning. Further thought leads me to inquire if the ends of horizontal branches might not be turned upwards, and the form of the tree be so changed without much wasteful destruction of fruiting wood? Certainly this could be managed upon many trees with comparatively young and pliant growth, but older rigid growth would have to be cut as in fig. 100. Trees so converted would not for a while look so well as a finished palmette verrier; but this is clearly a case wherein utility stands before appearance, and the end and aim of fruit culture—the production of full crops of fine fruit upon healthy trees—has to be kept well to the fore. If, therefore, it is possible so to alter and improve a faulty form of training, it certainly ought to be done.

But says "A Thinker," "I cannot see clearly how the space between two trees could be occupied after some feet had been cut from the larger branches and the resultant growths trained vertically." Has my critic never seen a cordon? and is he aware how quickly those invaluable little trees come into bearing? Planted 18 inches apart they soon fill every foot of space assigned them, not as mere makeshifts, but as really valuable fruit trees. I hope next planting season to plant at least one row of espalier cordons, and take this opportunity of recording my opinion that cordons are the best—better even than palmette verriers for espaliers, and, with one or two exceptions, for walls. My exceptions are Peaches and Nectarines, and perhaps Figs, and yet I really cannot see why Fig cordons cannot be managed as well as any other sort of fruit. What we require in a Fig tree is plenty of short-jointed stout lateral growth, every such shoot of a Brown Turkey or Brunswick giving two or three Figs from the upper buds upon open walls, and under glass other sorts do so too. Compare the points of merit in a cordon with those of any other form, and see how much may be said in its favour. It requires so little space that a failure is made good without materially affecting the fruit supply; it comes quickly into fruit-bearing, and yields fruit of high excellence in size, form, colour, and flavour. It is true that a single cordon cannot yield much fruit, but I believe it will be found that five diagonal cordons trained upon wires to a height of 6 feet 6 inches will, when fully developed and in full bearing, give a bushel of Apples. Although I cannot speak positively here, yet my assertion is not mere guesswork, but it is based upon fairly reliable data. Much

more serious is the loss of a palmette verrier; the work of eight or ten years is not only lost, but the huge gap in the line of espaliers is a disfigurement which is best got rid of by planting the more useful cordon.

Spur-development is a matter of the highest importance, requiring intelligent and watchful care. No hard-and-fast rule can be safely applied to it. Compare the growth of a Margil or Keswick Codlin with that of Bedfordshire Foundling or Warner's King Apple, and it will be seen that while the first two may perhaps be restricted to 6-inch spurs or thereabouts, the more rampant growers may advantageously have longer spurs. Six inches! why I have seen many an Apple measuring nearly as much as that in diameter, and how many of such fruits would "A Thinker" produce upon his puny spurs? To test the matter I have just been to a Margil tree, and found a spur slightly over a foot long with twelve clusters of fruit upon it. I opine that a few such spurs would go very far towards winning that medal, albeit I am perfectly content to have the fruit without the medal. I am strongly of opinion that there is by far too much fastidious refinement about spurs and precision of growth. I have seen both tree-lifting and pruning carried to a ridiculous and hurtful extreme, and again say, Let us treat each tree according to its requirements, and not by line and rule.—EDWARD LUCKHURST.

THE CUCUMBER DISEASE.

ON page 476 the above troublesome pest is alluded to, and I can well pity anyone having to battle with it, and at the same time expected to keep up a supply of fruits. For two years, 1881 and 1882, we had it here. It made its appearance about June in the Cucumber house. Fresh seed and soil were obtained, and another house that had not had Cucumbers in it for at least five years was devoted to them; but no sooner had the small fruits appeared than they were attacked, and no good Cucumbers were cut. Some plants were also put out in new three-light frames, and they also were attacked. Vegetable Marrows also shared the same fate towards August, the Custard Marrow in particular being worse than the Long White sort; but strange to say, a house full of Melons of three varieties next to the Cucumber house escaped altogether, not a trace of it was seen. Although fumigating and disinfecting with tobacco paper and sulphur was tried at the end of the season, the following summer it made its appearance again, but not in so virulent a form, and its not attacking the Marrows outdoors I attributed to a warmer summer than the previous one and less rain. I also employed more fire heat and damped the Cucumber house less of an afternoon with beneficial results; the extra 10° or so with less moisture seemed to arrest the disease. At the end of the season, however, I determined to give the house a more thorough disinfecting, and not have a Cucurbitaceous plant on the place if possible for the disease to exist on for at least four months, and I am glad to say that since that time (the last two seasons) I have not been troubled with it.

When the Cucumbers were cleared out and burnt in October about 2 lbs. of sulphur with a handful of tobacco powder was placed on the red-hot pan of a fire shovel. It was then put in the house and allowed to burn itself out. The house was kept closed for two days, and all insects and plants, such as woodlice and small Ferns on the wall sides, were killed. After that about a half gallon of paraffin and plenty of softsoapy hot water was used in scrubbing the glass and woodwork, and when thoroughly dried the house was used till the following March for miscellaneous plants, such as Cyclamens, Pelargoniums, and Primulas, and since that time I am glad to say I have not been troubled with the disease.

Increase of fire heat, with less atmospheric moisture, I believe is the best preventive for the Cucumber disease. Dryness at the root, however, must be avoided, or mildew and red spider will be encouraged. When the disease was with me at its worst I showed specimens of it to an eminent cryptogamic botanist and authority on diseases of plants, but he could give me no certain cure for it.—A. HARDING, *Orton Hall Gardens*.

PYRETHRUMS.

THERE is no question that single Pyrethrums are preferred to the double varieties for their simplicity and brightness of colour, the florets exhibiting the striking distinctness of tint around the golden disc with an elegance of form which renders them useful when far in advance of the double varieties. The effect of the single forms in a mass is very striking, and they lose nothing by being seen under artificial light. In brief, the single Pyrethrums are in early summer

what the single Dahlias are at a later period, not the least of their charms being their handsome Fern-like foliage, and they are even hardier and more free growing than the double varieties. If the single varieties are beautiful—and they have only to be grown to be appreciated—the double varieties are indispensable in every garden for producing a grand effect in early June; whilst for cutting they are invaluable, whether for associating with other flowers in vases or as specimens in glasses. The flowers are far more handsome than Asters, albeit they are not rivals, as they come in so much earlier, and are in June what the Chrysanthemum is in November.

Pyrethrums are hardy, but they will not grow in every soil or in every position. In a wet or heavy soil they will not succeed, and in shade or in shrubby borders they are useless. It is no use planting in a wet soil without first draining it, or where the soil is heavy without making it porous by the addition of old lime rubbish, sand, gravel, &c.; nor in shrubby borders unless the situation be sunny and the soil not permeated through and through by the roots of the trees and shrubs. Pyrethrums like a good friable loam and liberal treatment, watering with liquid manure freely in dry weather. In autumn a top-dressing should be given of decayed manure or thoroughly decomposed matter from the rubbish heap, and in March it may be neatly pointed in. Early in May a good watering should be given if the weather be dry, and the surface mulched with manure a couple of inches thick, with good supplies of water or liquid manure once a week unless the weather be wet. When extra fine blooms are desired the stems should be thinned as soon as they show their flowers, leaving the strongest and most promising only. After flowering remove the old stems, and the second growth will be strong, some of it continuing to give flowers in late summer up to frost. Slugs are very partial to the growths, eating them off within the ground during the winter. Where these pests abound it is a good plan to remove the soil about the crowns in autumn, dusting with quicklime, and apply a layer of sharp ashes.

Propagation is effected by division, which is best done in spring. Each part taken off with a portion of roots will grow if duly attended to with water. The rootless portion may be potted singly and plunged in ashes in a cold frame, kept close and shaded from sun until established, when they should be gradually hardened. The best means of propagation, however, is by cuttings in summer directly after flowering, at which time the plants form fresh growths. Take off each cutting with a portion of the root-stem, and insert it to the base of the leaves in light sandy soil in 3-inch pots, plunging them in ashes in a cold frame, keeping them moist and shaded, damping them every morning through a fine rose. A little ventilation may be given in dull weather, and when rooted and growing freely gradually harden them. The plants so raised may be placed out in September in prepared beds or in the borders, or they may be wintered in a sheltered position plunged over the rim of the pots in ashes, transferring them to the flowering quarters in spring; but the plants are best put out as soon as they are well rooted, allowing 18 to 24 inches distance between them. Some of the best varieties are the following—

Single-flowered.—Grandiflorum, rosy earmine; very striking and large. Bellona, brilliant red; very clear and good. Ruby, rosy purple, shaded carmine; a telling colour. Warei, very rich carmine and crimson; extra. Coccineum, reddish purple; fine flower. Vivid, amaranth; very bright and fine. Kleinholtz, crimson; very large. Hamlet, deep pink; very good. Orlando, bright red. Vanity Fair, deep pink; large. Fairy, flesh; good. Emblem, rosy lilac; very large and telling. Virginal, white; of good substance.

Double-flowered.—White Aster, the best and largest of the whites. Mont Blanc, white; very free and fine. Olivia, very large, white. La Vestal, blush; large, extra. Nancy, blush and white, or blush white shaded salmon; fine. Lady Derby, silvery flesh; very pleasing. Madame Billiard, pale flesh; fine flower. Dr. Livingstone, flesh; very good. Gustave Heitz, rosy pink; fine flower. J. N. Twerdy, bright red; fine. Captain Nares, brilliant crimson; fine. Progress, deep red; fine. Nemesis, rose, tipped crimson. Ne Plus Ultra, lilac; large and fine. Captain Boyton, carmine, edged white. Imbriatum, carmine, tipped white. Haage et Schmidt, carmine in outer petals, rose and white centre; fine. Le Dante, rose, tinged orange. Globe, outer petals rosy lilac, centre deep rose; fine. Emile Lemoine, crimson, tipped gold. Panorama, blush, tipped yellow. Vance, creamy yellow, tinged flesh. Solfaterre, sulphur; distinct and fine.—G. ABBEY.

EARLY PEACHES AND NECTARINES IN POTS.

OWING to insufficient artificial heat we have no real early Peach house here, and our first fruits from ordinary trees cannot as a rule be gathered or ripened before July, but of late and in May we have had quantities of ripe Peaches and Nectarines from trees in pots. These were bought in two years ago from Messrs. Smith of Wor-

eester, and although they did well last spring, or—that is, in 1883, we did not try to crop them to the utmost then, but this season they have been bearing fully. Half a dozen were placed in an out-of-the-way corner in a Pine house in January last, and here they flowered freely, set a capital crop, and swelled to our satisfaction. Some of the little Nectarine trees growing in a 10-inch pot produced as many as seventy well-developed fruits, and we found them all most acceptable.

This plan of introducing a few pot trees in order to secure early fruit is a capital one, and should be generally practised by all who have no special early Peach house. It is quite a simple arrangement placing pot trees in the corners of warm houses in spring, as with a little care they will succeed in such situations perhaps beyond expectations. Early in spring, when the flowers are open, they require to be brushed over daily, then insects must be kept down with the syringe; but the most important of all is to keep the plants well watered at the roots. There must be no fluctuation in this. Once too dry is ruinous, as it checks growth, and not unfrequently causes the fruit to fall; but it is easy enough to keep the soil and roots moist by watering from once to three or four times a day, according to the heat and aridity experienced. When the fruits are newly formed they should not be hurried on by stimulants, but as soon as they have formed their stones liquid manure may be applied every alternate day, and a change of food is beneficial. Sometimes we water ours from the cow manure tank, then they have a little guano, and all such is given in a weak diluted state.

As soon as the fruit has been gathered attention must not cease; on the contrary, it is just at this time that they must be well attended to, that a good crop may follow next year. In bringing the trees from a warm house they should be gradually hardened until they can be finally placed in the open air in July. Then they should be in a sunny position, with the pots plunged to the rims in ashes, and water must be given freely whenever it is required.—K. G.

NOTES FROM MY GARDEN IN 1883.

HERBACEOUS BORDERS AND ROCKERY.

THERE is nothing in my garden that gives me a greater amount of pleasure than do those portions devoted to hardy plants, for the pleasure is not that of a few weeks, but lasts throughout the entire season. From early spring to late autumn there is always something to be seen, something to admire; and as I can recall the time when, following the stream, I used my space and time for the collection of bedding plants, and gazed for many months on empty beds, where now I have always something, if not in flower, at any rate green, and fresh, and promising some future enjoyment, I can appreciate the change which has taken place in this style of gardening during the past few years; and while there may be danger in running, as we are so apt to do, into extremes in England, yet has the change been of immense benefit to gardening, and an especial boon to those who only possess small gardens.

We were wont to regard the Snowdrop as the earliest harbinger of spring; but long ere the Snowdrop had opened, beautiful clumps of *Cyclamen vernal* and *Atkinsii* rejoiced our eyes with their pretty blooms and foliage. By-the-by, is it certain that *Atkinsii* is anything more than a variation? Mr. Atkins of Painswick (lately deceased) crossed *vernum* with *persicum*, and hence obtained this variety; but may it not have been, as in many instances, that the crossing failed? I cannot trace a shade of *persicum* in it, and as that is not hardy, which certainly *Atkinsii* is, it gives colour to the notion that Nature was more powerful than the hybridiser. Then immediately after that came that very fine Snowdrop, *Galanthus Elwesii*, far superior to the common Snowdrop of our gardens in the size of its flowers, and, as far as my experience goes, earlier. With this also were associated *Crocus Imperati* and a few others. *Hepaticas* are with me a failure, why I do not know; but even *H. angulosa* has not done well, and its blooms have been invariably eaten off by slugs before they are fully developed. Then came at nearly the same time delightful clumps of the lovely *Chionodoxa Lucilæ*. I cannot understand anyone thinking lightly of this lovely gem if they succeed in growing it. Every year seems with me to increase its value. At first it had only two or three flowers on a stem, now it is to be seen with seven, and a friend informs me that he has had one with eleven on it; then, as the smallest bulb blooms, as each clump increases in size the blooms are more numerous. Beds of it are very beautiful, and I do not think it is any disparagement to the older *Scilla siberica* to say that it rivals if not excels it.

I am not sufficiently affected by the Daffodil mania to go into ecstasies over them. They are doubtless very beautiful, and add a great charm to our early flowers, but as to going in for a collection of them as a collection I do not see it quite yet. In the little paddock in front of my house the common double Daffodil has established itself, and various patches of it in the Lenten season have a very pretty effect. I notice each year an increase in the number of clumps. How does this arise? Being meadow it is never disturbed, and consequently as the clumps are some distance from one another I do not quite understand how this increase is effected. *Narcissus minor* I have found to be a great favourite with slugs, and unless carefully watched none of the blooms escapes their ravages. I have a few of the incomparabilis section, and some of the *Leedsii* seedlings, but with that exception I have not much

in the way of variety. Perhaps I may this year increase my number. Along with these I have dotted over the border clumps of *Hyacinths* in mixed colours. As I each year grew some sixty or seventy of imported bulbs, these are then planted in the borders, and I have very often very fine blooms, and are very gay. There is in my Rose border a clump all the produce of one bulb, which was planted there some eight or ten years ago, and this year it had nine trusses, and many of them of good size. After these have passed away clumps of *Narcissus poeticus* and *Gesneriana Tulips* make the border look pretty, but there is then a little gap, when the *Aquilegias* of various kinds, hybrids and others, come into flower, and *Papaver orientale* shows its brilliant blooms: then again all looks gay. In the end of June and onwards some grand clumps of *Liliums* begin to develop themselves—*testaceum*, *dalmaticum*, *incomparabile*, and *Sappho*; *pomponium*, the old Orange Lily, the grand old Tiger, *Szovitzianum*, *Batemanniae*, *Michauxi*, and others, until we come to *L. speciosum* and *auratum*; and then when the grand spikes of *Delphiniums* from 6 to 7 feet high develop themselves how grandly gay the garden is! I always plant out a few of the coloured-leaved *Pelargoniums*, so that they fill up the gaps formed by the bulbs which have lost their foliage. And so on through *Pyrethrums* single and double, single *Dahlias*, &c., we have a succession of gay and fragrant blooms, for I cannot do without the old-fashioned Sweet Pea, Lavender, and Mignonette. Most of the plants that I have named and many others will flourish in almost any garden, with the exception of Lilies, whose culture on such soil as the London clay is almost hopeless. I must not omit to mention some plants which are rarely seen amongst us, but of which I had four years ago half a dozen bulbs from Messrs. Souillard & Brunelet of Fontainebleau, the successors of Mons. Souchet—the hardy varieties of *Amaryllis vittata*, one of which threw up a fine spike of bloom last year, and which I sent to the Floral Committee of the Royal Horticultural Society, but, unfortunately, the letter I sent with it miscarried, and so no notice was taken of it. They stood through the two severe winters of 1880 and 1881, so I reasonably conclude they are hardy, in the south-east of England at any rate. They are very showy, and certainly deserving of more consideration than they seem to have received as yet.

My small rockery has been a great delight to me, especially during the early months of the year, and the following did very well:—*Ramondia pyrenaica* has spread and made quite a little colony for itself, and flowered exceedingly well. It is so very pretty that those who have even the smallest rockeries should try it. It likes heat, which I cannot well give it, quite a shady position, but even in my too sunny position it has done well. *Saxifraga oppositifolia*, which I had oftentimes tried to establish, but in vain, has at last done well, and promises to make a good clump, and as it is one of the earliest flowering plants we have, it is satisfactory to be able at last to get it to do well. In May, when large clumps of *Aubrietia* (Ingram's variety), *Iberis coriacea*, one of the very whitest flowers we have; *Phlox verna* and *setacea*, the pink Rock Roses, and the yellow *Potentilla* were in flower at one time, it was as pretty a piece of colouring on a small scale as we would desire to see. Another plant about which I had some doubts as to its flowering was the Himalayan *Androsace sarmentosa*, but it has redeemed its character and bloomed from every rosette, while it is spreading widely. It is excessively pretty in all its stages, whether in its pretty Saxifrage-like rosettes in winter (when it is better to place a glass over it), or in spring when it sends up its pretty little pink flowers. My clump of *Cypripedium spectabile* has again increased. It flowered very freely, and evidently likes its position, which is not, however, so moist as I should like for it. *Oethionema grandiflora* did very well, and was full of bloom; but for some reason or other my *Trilliums* have not flourished. I must endeavour again to try them, for I think *T. grandiflorum* one of the prettiest spring flowers that we have.

I have not by any means exhausted the number of the plants which have given me so much pleasure in the herbaceous border and the rockery, and it is astonishing what a number of different species we may grow in a small garden if one is content with a single clump of them, and how much pleasure one may derive from the beginning to the end of the season. Happily the taste is widely increasing, and there is not much need now to encourage people to try to grow them; and while we encourage the old-fashioned flowers of our forefathers, let us not forget that the zeal and energy of our nurserymen have added numbers of beautiful plants of which they knew nothing.—D., Deal.

PRUNING ROSES.

SOMEBODY has sent me this day (June 12th), the *Journal of Horticulture* dated May 1st. I expected one dated June 12th, and did not discover the ancient date until I had read it through, but was rather puzzled that there should be a letter about pruning Roses so late in the season. The letter is signed "A. C." I, like "A. C.," am an advocate for early pruning, but not quite so early as he commences. In our latitude and longitude I reckon March 7th about the right day to begin. I did so this year, and about the middle of April the buds were looking plump, and some had started into shoots about 2 or 3 inches long. Then came the frost, and about the end of May I found the tops of the pruned branches looked miserable; the leading shoot killed outright, and the buds below, instead of breaking into strong shoots, breaking out in frizzled bunches. I have had to prune them all again down to the first strong-growing healthy shoots, and my blooms I reckon will have been retarded a week or ten days. A Bedfordshire friend (perhaps the best Rose-grower in Bedfordshire) called on me a few days ago, and rejoiced to say that he had not pruned a single plant in his garden before the disastrous frosts

of April 21st to 23rd, and now his plants were looking very promising and growing vigorously, and I am inclined to think that late pruning is safer than early pruning.—F. H. G.

STAPELIAS.

THIS is a large genus belonging to the order Asclepiadaceæ, most of the species producing fantastic and brilliantly marked flowers. However, there is no denying the fact that at the present time Stapelias are not popular; indeed, very few know them, therefore I consider them worthy of special attention. I have always considered the taste for and introduction of Orchids to have been one of the reasons for Stapelias going out of fashion, which I will endeavour to explain: thus, when Orchids began to be understood, it was found that the smoke-flue-heated stoves did not suit their requirements, because living in and drawing their nourishment entirely from the moisture of the air, the dry atmosphere generated by the flue was not congenial to their wants, and from that time hot-water pipes rapidly took their places. Now, it so happens that the atmosphere produced by the smoke-flue is the most congenial to the plants under consideration, or at least I have never seen them growing in such perfection under any other conditions. Stapelias, however, have another defect; and that is, instead of yielding a fragrant perfume, or being altogether scentless, they give off a very offensive odour, but if grown upon shelves in the house this becomes less perceptible. They must not be considered stove, but rather warm greenhouse plants, and as we must perforce again see many of the fine-flowering Cactuses in our plant houses, the Stapelias and they will find a dry warm corner of the greenhouse set apart for them.

The genus was named by Linnæus in memory of a Dutch physician, one Bodæus Stapel, and to the celebrated and successful collector Masson we are indebted for the majority of the species which were introduced towards the end of the last and beginning of the present century. Stapelias have been sub-divided by Haworth, but for convenience sake we shall here take a general view of them.

These plants are easily cultivated. Drain well, pot in light sandy loam, adding sand and old rough brick rubbish. At all times they should be carefully, and even sparingly watered, but during the winter months very little indeed will suffice. When growing in spring keep them in a close greenhouse or the cool end of a dry stove; in summer an ordinary airy greenhouse will suit them best, but in autumn a dry warm nook is necessary in order to encourage them to develop their flowers.

The following is a list of the most distinct species, all of which are natives of the Cape of Good Hope, except where otherwise stated. The dates following the description indicates the year of introduction.

S. bufonia.—A peculiar plant with erect stems, and branches simple, obtusely four-angled, as are most of the species. Spines cross-like. Corolla flat, with no tube, five-lobed; lobes spreading, acute. Ground colour yellow, spotted all over with lines of brown spots. 1806.

S. variegata.—This, like the preceding species, belongs to Haworth's sub-genus Orbea. It is a very showy plant, and is well shown in the wood-cut (fig. 112). Stems obtusely angled, bearing a few distant spines. The flowers are large, the corolla being five-lobed, spreading; lobes ovate-acuminate, and the colour is bright yellow, irregularly but profusely blotched with cinnamon. 1727.

S. vetula.—Stems branching, smooth; teeth rounded. Corolla flat, with lobes lanceolate-obtuse. Colour heavy purple, with a few lines of a lighter hue. 1800.

S. pedunculata.—A beautiful free-flowering species, belonging to Haworth's sub-genus Caruncularia. Stems almost cylindrical. Footstalks very long and pendulous. The corolla segments are lanceolate with revolute margins, the colour being reddish purple, paler at the base, and fringed in the angles. Cape of Good Hope. 1784.

S. sororia.—This is a truly beautiful species, having branches furnished with acute incurved teeth and pendulous flowers. The corolla is reflexed, oblong-lanceolate, purplish brown, each lobe having a patch of yellow at the base, which is transversely barred with reddish purple; margins of the lobes ciliated with long brown hairs. 1797.

S. Plantii.—Of somewhat recent introduction, bearing out our assertion that the colony from which we received it must have many treasures yet to yield us. Stems creeping. Branches erect; angles furnished with short incurved spines and short footstalks. The corollas are reflexed 4 to 5 inches in diameter; the lobes ovate-lanceolate, purplish brown, transversely barred with irregular lines of light yellow, and having an uninterrupted marginal band of chocolate-brown. The margins are fringed with long light-coloured hairs. Native of Natal. 1866.

S. grandiflora.—At once a grand and singular flower. The corolla is 4 to 6 inches in diameter, the lobes lanceolate acute. The centre and nearly the whole of the segments are densely clothed with long fine silky hairs of a reddish purple hue. The tips of the segments are naked, blackish purple, the margins being ciliated with long white hairs. 1795.

S. Asterias.—The flowers of this species bear a wonderful resemblance to a star-fish. The corollas are five-lobed with lanceolate lobes. The margins are revolute and ciliate. The colour is deeply purple, transversely streaked with irregular wavy lines of a paler hue. 1795.

S. pulvinata.—Stems decumbent. Flowers 4 to 5 inches in diameter, five-lobed; lobes broad, sub-rotund, somewhat wrinkled, acuminate; the ground colour yellow, transversely banded with irregular lines of dull purple. The tips of the segments are dull brown, banded the same as the larger portion. The margins are densely fringed with purple hairs, the centre of flower being profusely clothed with long reddish brown hairs. 1795.

S. verrucosa.—Stems reclinate. The corolla is flat with recurved segments, the colour being yellow spotted with reddish purple; the centre of the flower elevated, warty. It belongs to Haworth's section Podanthes. 1795.

S. picta.—A dwarf-growing beautiful species. Flowers on long drooping peduncles. Lobes of corolla flat and spreading, ovate-acuminate, slightly wrinkled. The ground colour purplish crimson, irregularly marbled with yellow. 1799.

S. revoluta.—This beautiful species belongs to the section Tromotriche, Stems erect, very little branched; teeth blunt and spreading. Flowers on short footstalks. Corolla very fleshy; segments revolute, the margins prettily

decorated with club-shaped black hairs. The centre of the flower is pale yellow, the lobes reddish purple. 1790.

S. lentiginosa.—Stems five-angled, with swollen spreading tooth-like angles furnished with short hook-like spines. The corolla is sub-campanulate, five-lobed, with a little point in the centre of the wing between the lobes. Ground colour of yellowish white irregularly spotted and blotched with crimson. 1800.

S. reticulata.—This is nearly allied to the preceding. Stem five-angled, much-toothed; teeth spreading. Corolla sub-campanulate, having five little points between the five lobes, thus almost making the corolla appear to be ten-lobed. Colour yellowish white, profusely though irregularly blotched with dull purple. 1809.

S. campanulata.—Stems erect; teeth sharp and spreading. The corolla funnel-shaped; limb five-lobed; segments triangular and acute, with five smaller points between the lobes. Ground colour yellowish white, irregularly dotted and spotted with purple. 1809.

S. glauca.—The stems of this species are glaucous, with a five-lobed revolute

Fig. 112.—*Stapelia variegata*.

corolla. The lobes are ovate-acute, fringed on the margins with clavate hairs, the colour being reddish purple. 1799.

S. polita.—This is a charming little species belonging to Haworth's section Duvalia. Stems reclinate, six-angled and toothed; angles obtuse, furnished with long spreading teeth, with an additional minute one on each side at their base. Flowers two to four. Corolla five-lobed; segments ovate-acuminate; colour brownish purple; margins furnished near the base with long blackish purple hairs.

S. hystrix.—A beautiful species of recent introduction. The stems are freely branched, slightly glaucous, five-angled; angles obtuse, furnished with spreading teeth. Flowers mostly produced in pairs. Corolla spreading five-lobed; segments ovate-acuminate, recurved at the points; ground colour pale yellow, transversely banded with short lines of reddish purple; the lobes thickly studded with small erect fleshy points, which are also tipped with the same colour. S. E. Africa. 1869.—W. G. T.

SUMMARY OF WEATHER OBSERVATIONS AT HODSOCK PRIORY, NEAR WORKSOP, NOTTS, FOR MAY.—Total duration of sunshine in the month, 291.2 hours, or 42 per cent. of possible duration; there were five sunless days. Total rainfall, 0.84 inch; rain fell on ten days. Mean temperature of month, 51.5°. Maximum on the 11th, 77.0°; minimum on the 27th, 30.7°; maximum in sun on the 11th, 127.1°;

minimum on grass on 27th, 26.1°. Warmest day the 11th; coldest day the 1st. Mean temperature of the air at 9 A.M., 54.1°; mean temperature of soil 1 foot deep, 52.5°; nights below 32° in shade, 1; on grass, 8. Wind principally from W. to S.W. Temperature about the average, and similar to last three years. Rain less than in any May since 1876, and less than in any month since April, 1881; the greater part of what fell came in the first week. Sunshine more than in the same month last year, but more than in the two previous years. The country was getting rather dry, and rain wanted at the end of the month. Queen wasps very plentiful.—J. MALLENDER.

GATHERING FRUIT.

In all gardens, especially where many small fruits are grown, much time is occupied at this season in gathering fruit. It is work which will permit no delay, and we often feel annoyed, when other operations are pressing, that we have to turn all hands into the Strawberry, Currant, and Raspberry quarters day after day and in the best of weather. The latter is a point of the greatest importance, and cannot be too emphatically stated at the outset. There are many good housewives who buy quantities of fruit, boil their jam the right time, put in the requisite quantity of sugar, and yet they cannot get it to thicken properly or keep for any length of time without fermenting or moulding. All this in nine cases out of ten is caused by the fruit being gathered when wet and not being properly dried before preserving. Fruit bought in markets may often have been wet when gathered without buyers knowing it, and it will only be indicated or detected when the jam becomes bad; but in private gardens, where the fruit should always be gathered and taken direct to the preserving quarters, any loss through gathering it in a wet condition should never occur. Fruit gathered and immediately used for tarts is often collected in a wet state, and there is no help for this, as the demand for fruit for this purpose comes to us on wet days as well as on dry ones; but little or no harm results from this, as, unless the fruit has been wet for a long time, the flavour does not suffer. Raspberries are the worst fruit to deal with when wet, as they absorb so much water.

In all cases where the fruit can be preserved without having to be taken a distance, it is best to allow it to become quite ripe; but when it has to be carted, sent by rail, or carried in any way some miles, it is an advantage to gather it before it becomes "dead ripe." When it is well coloured but firm is the best condition of all to gather fruit for transit. Strawberries, Raspberries, and Red and White Currants, which are all very juicy when quite ripe, should in that case be gathered and placed in trays or dishes, which will prevent any of the juice being lost. Gooseberries and Black Currants will do in baskets. As a rule the morning is the best time to gather small fruits, and in market gardens much of it has to be gathered with the dew on it; but in private gardens, and in all cases where there is no particular reason for gathering it so early, none should be touched until the dew has evaporated. For this reason it is seldom that we can gather fruit before breakfast, but from nine o'clock until one or two o'clock we gather large quantities. Punnets, small baskets of various sorts, and 6-inch flower pots are all suitable in which to collect small fruits, to be emptied at the ends of the quarters into larger receptacles. We have never any call for a statement of the quantities of fruit collected and sent to the mansion during the season, but this does not prevent us booking every pound or quart of it, as I like to compare one season's quantity with another, and the dates of gathering; and I would advise all to keep a similar account, whether their employers may wish to see it or not.

All Strawberries, Black Currants, and Raspberries for preserving should be gathered without the stems, and so should Black Currants, the stems only being required on when gathered for dessert. When the fruit is gathered clean and carefully it saves much work in the kitchen. As a rule it is much better to go over the quarters frequently, say every alternate day in the ripening season, to collect it fresh and good, than to allow a large quantity to ripen and then make a large gathering. In this case much of it may be over-ripe, and make an unprofitable mixture with that less ripe.

Plums, whether on standard or wall trees, should be gathered before any decay commences, or just when they are soft all through and on both sides. The same remarks apply to Peaches, Nectarines, and Apricots, and there should always be a decided objection to any one pressing their fingers round these to feel if they are ripe. Many fine fruits are damaged in this way. The best way of testing them is to pull them gently forward; if they come away freely from the footstalk they are ripe, if not leave them. With these, as with all other fruits, it is of the utmost importance that they be gathered when quite dry and sound.—A KITCHEN GARDENER.

AUSTRALIAN HORTICULTURE.—In New South Wales the flower garden is more readily and successfully managed than in England,

although in the more elevated regions of the Colony the more tender kinds of plants have to be protected from the effects of frost at night. Every description of garden flower known in the United Kingdom thrives in the most luxuriant manner; the common Scarlet Pelargonium frequently attaining the proportions of a large bush, and blossoming the greater part of the year. The Sweetbriar, if allowed to run wild, becomes a kind of horticultural pest, overrunning the garden in every direction. In shady positions Violets grow as readily as in English woods, losing none of the fragrance which have rendered them such universal favourites. Roses and Camellias are abundant, especially the latter, bouquets of which, consisting each of about a dozen large beautiful flowers, are hawked about the Sydney streets during the season at the price of 1s. each.

THE ONION MAGGOT.

THE attack of the maggot of the Onion fly (*Anthomyia Ceparum*) has caused great havoc for many years, and nearly all methods of "remedy" have failed. Once the bed is attacked the Onions decay and the leaves turn yellow. All the Onions thus attacked should be at once lifted from the bed and destroyed. The earth should be attached to the bulb, and a knife is the best thing to use. It should be put under the bulb of the Onion, and the earth around the bulb lifted. If the Onion is only pulled up it is very probable that the rotten portion will remain in the ground, and that the maggot will stay there and develop into a mischievous egg-laying fly. This seems to be the only remedy once the Onion bed is attacked. The Onions must be lifted, and with the maggot in, then destroyed by burning. They must not be pulled and thrown on the path, for that is useless. After the attack all kinds of dressings are useless, and Miss Ormerod told me only last week that she found the fly that lays the eggs as lively as possible, and laying eggs in a crop covered with a dressing of soot. Before an attack a dressing of paraffin and water has been known to ward off an attack. Here it is believed that the efficacy of the dressing lies in the fact that the smell of the Onion crop is neutralised by the stronger smell of the dressing. It is well known that insects are attracted to their favourite crops by the smell, and attack frequently follows any thinning-out of the crop. This is not only the case with Onions, but also especially with Carrots, and in both cases paraffin (a wineglassful to a gallon of water) acts as a preventive by giving the crop an unattractive smell. The best preventive for the Onion crop is to sow the Onions in drills, and when the crop is young slightly earth them up. Unless the fly can get to the bulb, and there lay its eggs, it can do no damage, and if the drill is carefully earthed up the bulb of the Onion is protected during the time of attack. For nearly all crops a good preventive preparation of the land is a dressing of spent gas lime. This is a capital thing, and should be put on in the autumn and dug or ploughed in. If used fresh from the gasworks it must be put in when no crop is in, but if allowed to stand and lose its causticity it is perfectly harmless. It is a good thing, used caustic and fresh, to clear land of wireworm. It will kill nearly everything, but the earth soon destroys its causticity, and then in the form of gypsum it is a valuable manure.—HENRY F. MOORE, *Frome*.

CORNISH HORTICULTURE.

It now remains for me to make a few remarks respecting forcing flowers for market or other purposes. Forcing plants into flower is a phase of horticulture which has been for a long time practised. It is only within the past comparatively few years that it has become a matter of almost national importance, and that competition has become so keen and to such an extent which it has evidently now assumed. The number of persons of both sexes employed in the various departments of "flower-farming," even in this country, to say nothing of the continental ones, probably number several thousands. There is a much-hackneyed saying to the effect that where one man will live another would starve. The success of the former individual does not, perhaps, wholly rest on his being the more industrious, for ingenuity often gains half the battle. Knowing what is wanted and when it is wanted are both matters of great importance. To get a favourite flower in bloom two or three weeks before anyone else, and to be the first in the market with it, makes a great difference in the favour of the grower.

The plants most generally forced are Arum Lily (*Richardia æthiopica*), Belladonna Lily, Deutzia, Lily of the Valley, and Astilbe (*Spiræa japonica*). Large quantities of Arum Lily tubers are procured from various parts of this country and from the continent every year by the Cornish growers. This handsome semi-aquatic thrives with astonishing success in the open air, even through the severest of winters. It is grown in comparatively small pots, and forcing commences during winter, the roots being taken from the open ground, potted, and placed in a gentle heat in batches from early winter right on until the out-of-door plants commence to show flower, which is generally during April. One important item in the culture of this fine plant, and which is frequently overlooked, is that it can hardly have too much water when forcing; the soil in which it is grown may be kept constantly thoroughly saturated. Another consideration well worth mentioning is that the plant should not be overpotted, because when growing in a rich compost and in large pots the ends of the cultivator will in all probability be balked in securing little other than a foliaceous growth and a superabundance of large roots. For forcing, pots about 6 inches in diameter at the top will be found quite large enough. Gradual and gentle forcing is also very needful, as all sudden changes or a great heat will prove fatal to success.

Various named sorts of Narcissi are largely grown. The earliest one is, of course, the Paper White, which belongs to the Polyanthus group. It is obtained in bloom in the early part of winter, throughout which season it continues to produce its pure white and fragrant flowers. It requires only a gentle heat to start the bulbs into growth, and can be had early in the

season by growing it in an unheated structure, such as a frame or conservatory. Next comes the charming Poet's Narcissus (*N. poeticus*), with its pure white perianth and conspicuous red corona. This can be obtained in flower as early as February if placed in a warm atmosphere. I understand that Mr. T. S. Ware has several varieties, which he states will flower quite five or six weeks before the typical species. Whether this advantage would hold good to the same extent when grown under glass I am not in a position to state, but should be inclined to doubt it. A favourite with the growers of Scilly is the Orange Phoenix, one of the numerous varieties of *Narcissus incomparabilis*. It would be rash perhaps to call any one form the handsomest of all *Narcissi*, but the one just named certainly ranks very high among the best. The soft and delicate orange of the corona, and the sulphur colour of the very double perianth, are only secured by growing it under glass, with or without heat. When growing in the open air, exposed to all weather, and in a heavy soil, the corona assumes a very coarse orange tint, while the perianth is of an exceedingly dirty yellowish colour. There being plenty of substance in the flower, and as it lasts in beauty for a considerable time, it has been cultivated with much pecuniary success at Scilly, where it is grown by the acre, and the bulbs ploughed in something after the style of Potatoes. The flowers are packed in small baskets, and thus forwarded to various metropolitan and other markets.

The Lily of the Valley, although a "paying plant," does not seem to be forced to any great extent in Cornwall; and the methods there employed in its indoor culture are not likely to insure very much success with it. As a general rule, the crowns are set in boxes of sand, placed in a strong heat, and watered when the soil gets rather dry, the house having at the same time a dry or comparatively dry atmosphere. This method of cultivation is altogether an erroneous one. Success can only be obtained by placing the boxes containing the crowns over a properly constructed hot-water tank, and then closing the opening of the same perfectly close. The soil must at all times be completely saturated with water, and the atmosphere of the house kept as moist as possible. A bottom heat of from 95° to 100° may be maintained throughout. The boxes can be removed from the beds in about four or five weeks from the time when they were first placed therein. I have seen boxes having Lily of the Valley crowns with icicles hanging transferred at once into a moist bottom heat of nearly 100°, and with every success. The English three-year-old crowns of the German strain are far more likely to produce flowers before Christmas than those imported from Germany direct or the ordinary native sort; the experiences of other people may, however, be different.

The Belladonna Lily (*Amaryllis Belladonna*) is also grown extensively in various parts of Cornwall, but more especially at Scilly. Its large sweet-scented funnel-shaped blooms are extremely handsome, and the only drawback to the entire plant is that flowers and leaves are produced at entirely different seasons of the year—the former in autumn, and the latter in spring. It varies much in its colours, from nearly quite white to red, and sometimes two or three shades are produced in one flower. As it flowers in the autumn only, forcing is foreign to its nature; the supply, therefore, is wholly obtained from plants grown in the open air. In purchasing roots, large and solid ones only should be selected, and these should be in the ground before the end of August, or flowers will not be forthcoming until the following season. In cold districts it will be necessary to cover the roots with plenty of litter, but success will be impossible on a damp heavy soil, in whatever district.

Both *Dentzias* and *Spiræa japonica* are somewhat extensively grown for market purposes, the plants being usually imported from Germany; and the Ghent strain of *Azaleas* has been gradually proving to be fairly remunerative.

With the present article I conclude my brief sketch of Cornish horticulture in its several phases. I am quite confident that the resources of this county are vast and varied, and these, if backed up by the various elementary principles which are so essential to success in all branches of every industry, would serve to constitute Cornwall one of the richest and most important counties in England.—WILLIAM ROBERTS.

GRAPES SCALDING.

THE time is approaching when the scalding season may be said to be at its height, indeed it has begun already; so a word on the subject may not be unwelcome to any of your numerous readers who are in the position of amateurs beginning Grape culture, and who may, perhaps, be saved from various mishaps in their practice by taking note of the advice on all questions concerning the Vine that is tendered by various writers who have learned by experience how many difficulties attend Vine culture.

Scalding generally may be looked for when the Grapes begin to stone. Examine a berry or two, and if signs of stoning are seen keep the houses cool. If this is not done, especially in the case of Lady Downe's, serious damage will result if the weather be hot and sunny. The moment the first scalded berry is seen, ventilate at the top and side, and open the doors too if the temperature cannot be kept down.

The foliage should be allowed to cover every inch of the roof, so that the direct rays of the sun may be kept from striking on the bunches. Rather have an excess of foliage for the fortnight or so that the danger lasts than lose a lot of berries by the scalding that results from the sun striking the berries. As soon as the first signs of colouring are seen the amount of air given may be reduced, and gradually the temperature may be increased, till at the end of a week from the time the first coloured berry is seen the Vines may be having a good temperature, which will push them on and enable the grower to obtain well-finished Grapes.

By this means, however, endeavour to attain this increased temperature with a certain amount of air. Some amateurs known to the

writer have been found stewing their Vines in an atmosphere more like a vapour bath than anything else, the result being thin attenuated foliage and a general debility that told a very decided tale the following season—a tale of unfruitfulness not at all encouraging to the cultivator. Grape-scalding is essentially one evil in Vine culture that can be almost entirely prevented if the means are used in time.—S.

MITRARIA COCCINEA.

MITRARIA COCCINEA has the merit of being the only hardy plant of its order yet discovered. We do not, however, use the term "hardy" in its most extended sense; in very severe winters some protection would doubtless be necessary.

The habit and general appearance of the *Mitraria* will be sufficiently understood by a reference to our figure. Its stems are unusually slender, branched, and, in specimens of sufficient age, reach the height of about 3 feet. The foliage is small, and somewhat brittle and succulent, with a number of short hairs scattered over its upper surface. The flowers are numerous, and produced singly from the axil of the leaves, on footstalks 2 inches long, with a ventricose corolla, from the mouth of

Fig. 113.—*Mitraria coccinea*

which protrudes the long slender style. Its season of blooming extends from May to the end of June.

The soil most suitable for its cultivation is a mixture of good turfy peat and loam, in the proportion of three parts of the former to one of the latter. Where this is not at hand any soil containing a tolerably large proportion of leaf mould may be used, avoiding those of a poor sandy character, as well as pure loams deficient in decayed vegetable matter. When grown out of doors it must be planted under a north wall, or screened from the sun's influence by a fence, for it will not flourish except in the shade. Until its hardiness in the northern and eastern counties has been more fully tested we would not recommend its exposure during the winter months without some protection. A small handglass or a large inverted flower pot will offer a ready means of warding-off the effects of frost; and to these may be joined, as an auxiliary, a small heap of coal ashes. Where there is the convenience of a cold frame, the roots may be potted in the autumn and preserved with less risk.

If grown as a pot-plant it will be necessary to provide it with a cool shady window; and an arid atmosphere must at all times be avoided. Especial attention must be paid to the drainage, for the soil in which it appears to succeed best being of a retentive nature, too great

an excess of moisture must be guarded against by a good supply of broken crocks.

Gesneraceous plants, as well as all others with tuberous roots, usually require to be kept quite dry when at rest; but with the *Mitraria* a somewhat different treatment will be necessary, for its fibrous roots will not bear the complete withdrawal of moisture. It will, therefore, need an occasional watering during the winter months, though the soil must be kept only in a slightly moistened condition, and the plant should be placed in a cool situation—by no means in a warm apartment.

Its propagation presents no greater difficulties than that of the other plants of its order. The easiest mode of increasing it is by division of the roots in spring; but cuttings may also be taken at any time during the spring and summer months, and struck in any light vegetable soil under a bell glass or tumbler.

It is a native of the Island of Chiloe, a circumstance which will explain both its comparative hardiness and its preference for a cool moist atmosphere and partial shade.—W. T.

SYRINGING VINES IN BLOOM.

THIS has ever appeared to the writer a practice to be condemned when used with the idea of getting a good set. If any doubt exists in regard to the setting of any particular variety of Grape, a touch with a feather is much better; even a shake of the rods once or twice a day in the passing is a very effectual means of procuring a set. But a feather (ostrich if possible) tied to the end of a long stick, so that every bunch can be reached easily, is the best. When the Grapes come into bloom dust each bunch very lightly with the feather, and if every bunch is attended to in this way when it is in flower, it will be very strange if a grand set does not repay for the trouble.

Syringing Grapes the writer never practises, except perhaps for such varieties as Alicantes and Lady Downe's, which are the better for a dash with the syringe just before beginning to thin them, as they have a great amount of *debris* of their flowers always adhering among their berries. Great care should be taken that the water used be quite clean.

Occasionally when red spider has happened to get a hold in the early vineries the syringe has been used, but only as a last resource.—S.

THERE appears to be every probability of the INTERNATIONAL FORESTRY EXHIBITION AT EDINBURGH being very successful as regards the number of the exhibits. The Indian collection of wood alone is said to contain about 700 specimens.

— MR. DAVID HOUSTON is now delivering, on Wednesday afternoons, at the Crystal Palace, a series of ten lectures on our NATIVE TREES AND SHRUBS—a subject of great interest, and one which is comparatively rarely treated.

— IT is stated in the Report of the Metropolitan Board of Works that the LONDON PARKS AND COMMONS under their control amount to 1769 acres, the cost of managing which during the last year was £17,803.

— MR. T. LAXTON, Bedford, sends us flowers of his INVINCIBLE CARMINE SWEET PEA, which was certificated by the Royal Horticultural Society last year. It is described as the result of a cross between Invincible Scarlet and Invincible Black, and is much the finest we have seen, both in size of flowers and richness of colour. As the name indicates it is of a peculiarly deep carmine tint, quite distinct, the keel being lighter.

— THE BEDFORDSHIRE HORTICULTURAL SOCIETY'S first show will be held on July 16th in a field on the Bromham Road, Bedford. 180 classes are provided for plants, flowers, fruit, and vegetables, the prizes being mostly of small amount, ranging from £2 to 1s.

— MR. HARDING in the following note refers to the WEATHER AND THE CROPS NEAR PETERBOROUGH, and it indicates that the late rains, that were so welcome and beneficial in London and other places, were not general:—"This has been the driest season as yet since I have been here, nearly seven years. Very little rain has fallen during the last six weeks. Hay crops light. William I. Peas were picked on

a border the 31st of May, and a full picking of the same variety on open quarters ten days later. Apricots, Strawberries, and Currants have good crops, but all other fruit is scanty, although blossom was abundant."

— THE RICHMOND HORTICULTURAL SOCIETY'S SHOW is announced to be held in Old Deer Park on Thursday, June 26th. The usual liberal provision is made for plants, flowers, fruit, and vegetables, a large number of special prizes being also offered by the patrons and supporters of the Society.

— "J. R." finds the TROPHY TOMATO one of the best varieties for outdoor culture. He has tried several of the most recommended sorts, and now solely relies upon this for outdoor supplies.

— THE ODDFELLOWS' FLOWER SHOW AT FROME, SOMERSETSHIRE, is announced for August the 4th, when numerous prizes of a useful but miscellaneous character, such as books, glass ware, tea, coal, grocery, umbrellas, hams, hats, drapery, shoulder of mutton, &c. In connection with the Show three prizes are offered by Miss Ormerod for "the best specimens of food plants injured by insects, accompanied by samples of the insects injuring them, and a short written account of the insect attack and of the means of remedy or prevention adopted."

— GLADIOLUS BYZANTINUS is a valuable early and free-flowering species, which at this time of year is most attractive in borders. Its rich crimson-purple flowers are produced in great numbers, the scapes being densely clustered on strong roots. Any border that is not too damp suits it well.

— ARISTEA CAPITATA.—Is this fine old plant in cultivation now? It was a favourite with me many years ago, but I have quite lost sight of it. The flowers are of the most brilliant blue, with spreading petals, and are borne two or three dozen together, in rings on a tall spike. The foliage is flag-like. I believe it was one of Thunberg's finds, and was by him named *Moræa cærulea*.—L. W.

— THE BIRMINGHAM AND MIDLAND COUNTIES CHRYSANTHEMUM EXHIBITION is fixed for November 19th and 20th. The usual liberal prizes are offered, including the £10 first prize for the best forty-eight Chrysanthemum blooms, twenty-four incurved, and the same number of Japanese. Several special prizes are also contributed by Mr. Hans Niemand, Mr. T. B. Thomson, Messrs. Pope & Son, Messrs. Richard Smith & Co., and Mr. J. Tomkins.

— PSEUDOLARIX KÆMPFERI, of which dried specimens were shown at the last meeting of the Royal Horticultural Society's Scientific Committee, is one of the most handsome of Japanese Conifers, and it is regrettable that it continues so scarce in gardens. A beautiful example of it may be seen in the Royal Gardens, Kew, near the private path leading to the Curator's house.

— MR. JOHN FORBES, Buccleuch Nurseries, Hawick, N.B., sends us "a GATHERING OF PANSIES from a collection of named sorts," which comprise some lovely blooms, large, beautifully formed, richly and diversely coloured. The shades of violet, purple, crimson, maroon, orange, gold, and yellow are charming. The blooms are indeed some of the best we have seen.

— "J. J., Lancashire," sends us a small growth of DENDROBIUM PIERARDI, which has flowers of much larger size than we usually see them. They are 2½ inches in diameter, with lips over 1½ inch long. It is very handsome whether a variety or due to good culture. The same correspondent also mentions that "D. Pierardi latifolium, with forty-eight on one growth, is much admired," as undoubtedly it deserves.

— THE schedule of the BROCKHAM AMATEUR ROSE ASSOCIATION announces that the nineteenth annual Exhibition will be held at Broome Park on Monday, July 7th, when, in addition to prizes in thirteen classes, the value of which is not stated, the National Rose Society's gold medal and two silver medals will be competed for, the first-named being the leading prize in a class for six blooms of one variety, and the others for the best Hybrid Perpetual, Tea, or Noisette blooms. The schedule also gives a list of the eighteen previous shows, where they were held, and the amount of gate money taken, a list of Rose show fixtures for the present season, the names of the too-much-alike Roses, and the results of the Rose elections in this Journal of 1882 and 1883. From the financial report it appears that the Association has a favourable balance of £14, and is therefore in a satisfactory condition.

— MR. STEPHEN CASTLE, The Vineyard, West Lynn, writes : "By parcels post I send three trusses of the double pink variegated PELARGONIUM CHELSEA GEM. I cannot think how it is that this very beautiful useful variety is so seldom noted. I have a row in 48-pots in a cool vinery, and they have been covered with blooms the past two months, and are now as full as ever. I am very partial to this plant, the foliage being as striking as the flowers. It is of a very robust habit, making a fine exhibition plant. I have them in flower from thumb pots upwards in good condition. Fancy a row of five dozen in full beauty ! I have never failed to strike every cutting of this variety. It is also good for bedding." The variety is certainly a beautiful one, the trusses large, and the colour a bright pure pink. The leaves are neatly formed and evenly margined with white.

— THE same correspondent finds "LOBELIA EBOR very good indeed, the colour being a fine dark blue, and very true from seed. Great stress is always laid upon raising Lobelias from cuttings, which is right when cuttings can be had in plenty, but for my own part I would as soon have a batch of seedlings if the strain is good. I think great credit is due to Messrs. Cannell & Sons for sending out so true and good a sample of seed."

— PART 5 of the "ILLUSTRATED DICTIONARY OF GARDENING" continues the subjects from Asmina to Aubergine, with several woodcuts. Very full lists of Aspidiums and Aspleniums are given, with figures of the most distinct species.

— THE MELON, CHALFONT PARK FAVOURITE, shown by Mr. N. Herrin at Kensington last week, is a variety of some promise. It is true that Melons are now so numerous that it is not easy to obtain one that is really distinct and meritorious enough for the honour of a certificate, but the one in question possesses some qualities that recommend it to notice. In the first place the fruit is of moderate size, round, even, and beautifully netted—no mean recommendation. In the next the flesh is of good depth, and when in its best condition of a rich flavour. The juice of the fruit tasted by the members of the Committee was, however, found to be a little thin. A good indication of its merits was afforded at the Fruit and Vegetable Show held at Kensington on the 27th ult., when in a class of twenty-one exhibitors Mr. Herrin was placed first with a good fruit of this variety.

— CALIFORNIAN CONIFERÆ.—The forests frequently extend to the river banks, and are made up of many species, coniferous and deciduous trees being everywhere found in proximity. Among the cone-bearing trees, the Yellow Pine, *Pinus ponderosa*, the Incense Cedar, *Libocedrus decurrens*, and the grand Silver Fir, *Picea grandis*, are the most frequently seen on the valley floor. There are also noble specimens of the Douglas Spruce, *Abies Douglasii*, and Sugar Pine, *Pinus Lambertiana*, though these trees seem to prefer a higher latitude, and are found in abundance on the slopes and mountains about the valley. On the heights may be found, in addition, Jeffrey's Pine, *Pinus Jeffreyi*, the remarkable Tamarack Pine, *Pinus contorta*, the great forests of the lovely Silver Fir, *Picea amabilis*, the most regularly beautiful Conifer of the Sierras. Many people have an idea that the Sequoia is found at Yosemite. This is a mistake, for though the Big Tree, *Sequoia gigantea*, is a habitant of the Sierras, the nearest trees are found at the Mariposa Grove, thirty miles distant, with the exception of some isolated specimens on the Big Oak Flat road ; while the Redwood, *Sequoia sempervivens*, is confined exclusively to the coast range. — (*Vick's Magazine*.)

— "THE EUROPEAN BUTTERFLIES AND MOTHS," by W. F. Kirby, is the title of a new serial work just commenced by Messrs. Cassell & Co. It is to be issued monthly, the first part containing eight pages of letterpress and two plates, one being coloured and representing several familiar species of butterflies.

— THE PLAGUE OF CATERPILLARS IN SOUTH WALES.—A Cardiff correspondent writes that the great swarms of caterpillars which have suddenly appeared on the mountains in South Wales have produced an extraordinary sensation in that part of the country. The insects measure about 1½ inch in length, are of a brown colour with black stripes. The head, which is furnished with a pair of mandibles, is of a dark yellow colour. The insects are remarkably lively, and eat all the green herbage in the vicinity. Many of the farmers have fired the mountains with the view of destroying the insects, but the visitation is too wide-spread to allow of this expedient succeeding. The whole of the mountains lying

between the greater Rhonda and Maesteg, a distance of twelve miles, are literally swarming with the insects, as well as the ranges of mountains and valleys intervening. Millions of the insects are found buried in the peat holes, gutters, and mountain brooks in some of the localities. The crows feed on them, and it is feared that this will result in the pest being carried to the fertile valleys, and will there attack the young grain. Anxiety is felt lest the insectivorous pests should get into the wool of the sheep, and the flocks are being driven from the mountains to other districts.

NOTES AT KEW.

IN May and June, provided the weather be not excessively dry, the Royal Gardens at Kew can be seen to better advantage than at any other period of the year, and the people generally appear to be aware of this fact, for the 84,000 visitors there on Whit Monday were certainly not all botanists or gardeners. That so large a number of persons should elect to spend their holiday there is also a satisfactory indication of the increasing appreciation of beautiful gardens, for no attraction of the essentially popular character, not even a band, is provided or needed. The visitors are apparently content with admiring the bright handsome or curious flowers, the fresh green foliage of the trees, and in enjoying the varied walks with the park-like scenery of the pleasure grounds. Anyone can, indeed, pass a pleasant afternoon there at this time of year ; but the plant-lover will find abundance to interest him, and one of the first places he should direct his steps to is

THE ROCKERY—This is now becoming well furnished, and the appearance of newness being worn off, it is much more natural and pleasing. Especially prominent on a high mound near the northern entrance are some hundreds of Foxgloves, self-sown, of varied colours, and forming a little forest of flower stems that have a charming effect from many positions. Judiciously employed, Foxgloves are most valuable plants in gardens, particularly in such positions as the above—near woodland drives, in shrubberies, or wherever their pinnacles of flowers can be seen rising above other vegetation. On the Kew rockery it is undoubtedly the happiest feature at the present time. Worthy of particular notice also is a fine clump of *Aubrietia Hendersoni*, which has been covered with large deep purple flowers for the past three months, and seems likely to continue so for some time to come. It is not only one of the largest flowered varieties, but its colour is rich and constant, and the floriferous character is an especial recommendation. Why old comparatively insignificant forms of *Aubrietia deltoidea* should be grown for spring bedding, when so great an improvement as this can be obtained, it is hard to understand. The graceful dwarf *Campanula pulla*, which occupies a spacious nook, will soon be in its best condition, the small pendulous purple bells being fast expanding. Of the small-growing *Campanulas* this deserves more attention than it has yet received in gardens, especially where a rockery is prized. Hosts of other plants demand a note, but their claims must be unrecognised at present.

The herbaceous ground is similarly filled with attractions, nearly all the natural orders being represented by abundant flowers. The *Ranunculus* and Poppy relatives still contribute largely, amongst the latter being the massive rich *Papaver orientale* and the diminutive but pretty yellow *P. nudicaule*. The last-named, with its varieties *miniaturum* (deep orange) and *album* (white), forms a trio of attractive little plants that are invariably much admired. It is a great stride from these to the Labiate family, but there are found the next effective flowers amongst the *Anchusas* and *Echiums*. *E. italicum* is lovely now with hundreds of its brilliant blue flowers, forming quite a floral cone. The Iris garden is in excellent condition, and the plants seem quite satisfied with their position, judging by the vigorous manner in which they are growing and flowering. The charming Iris *neglecta* is flowering profusely, its blue-tinted and varied blooms. The strangely coloured *I. squalens* is attractive. *I. variegata* and many others prove how beautiful these plants are when well grown. To insure their success, however, well-prepared borders are necessary ; and though in few gardens, perhaps, could such elaborate preparation be made as at Kew, yet there is little difficulty in providing a well-drained position and a good depth of soil. Except that valuable town plant *Iris germanica* and its varieties, few of the Irises receive the attention they so well deserve.

The ferneries are always worth a visit, and an improvement quite recently effected in the cool house is likely to increase the health and beauty of the Filmy Ferns considerably. Everyone admires those delicate little gems of the *Hymenophyllum* and *Trichomanes* genera, and the Kew collection is so rich in rare

and beautiful species that it has long been a subject of regret that they were not better provided for. During many years they have been grown in small cases in the tropical house, and despite the best care they have never been quite satisfactory. Several causes have probably contributed to this state of affairs; but the most important are the excessive heat on that side of the house which is next to the boiler, and the other is that where near a door which, being frequently opened, admitted currents of dry or cold air. Both these would have a tendency to render the plants unduly dry at times, and such extremes would effectually prevent their successful progress. A much better site has now been chosen, and good hopes may be entertained of soon seeing the collection in most vigorous health. A wall case has been placed along one side of the cool vinery, with a slate back and moveable glass sashes in front. Some of the Ferns are planted out at the base of this or between those growing upon portions of Tree Fern stems, and no doubt the case will be quickly filled. At present, however, the slate back has a rather bare appearance; and a small portion, which has been covered with peat in a wire trellis so that small Ferns could be planted on it, is much preferable, though there is some difficulty about extending this the whole length owing to the space it occupies.

In the Orchid house cocoa-nut fibre is being employed as a moisture-holding material upon the side shelves, and it looks both neat and pleasing. A slightly sloping bank is formed, in which are placed inverted pots, the bases of which are just level with the surface of the fibre. The Orchids are stood upon these, and as the supporting pots are of different sizes they can be readily and suitably arranged. The choice of material for this purpose is a matter of importance; and though many different sorts have been tried by Orchid growers, I have not seen anything at once so neat and so likely to answer the purpose as this fibre. Small coal and coke are sometimes used, but they have a sombre appearance. The ordinary white spar is the prettiest when clean, but it soon becomes green and dirty; pebble stones are also suitable, but the fibre is preferable in all respects.

The temperate house is now, as indeed it always is, very beautiful, not with a great display of flowers, but all the plants seem to be so healthy, thrifty, and handsome, the general condition of the paths and borders indicate so much careful attention, that it is quite refreshing. The grand Dicksonias with magnificent crowns of fronds, the gigantic Araucarias, and the hosts of peculiar New Holland plants have a more than ordinary interest. There is, however, one plant that is particularly worthy of note, and that is a hybrid *Streptocarpus* that is likely to become a great favourite in gardens. It has been obtained by a cross between the well-known *S. floribundus* and *S. parviflorus*, and is strikingly intermediate in characters. *S. floribundus* has large purplish mauve flowers, produced in moderate numbers; *S. parviflorus* has small white flowers, which are borne most profusely, four to six on a spike, and sometimes twenty spikes to a root. In the hybrid this floriferous character has been preserved, the flowers being, however, larger than those of *S. parviflorus*, and the colour of *S. floribundus*. In pans the plants are charming, and with such abundant flowers are invaluable.—VISITOR.

VINES BLEEDING.

WITHOUT entering into any discussion as to the cause of Vines bleeding I wish to add a few observations which I think bear upon the subject. About fifteen months ago some mischievous person wounded the large clear stem of a Holly tree near our house. It appeared to have been done with the spike end of a pick, the wood as well as the bark being much injured. The wound has never healed, but, on the contrary, has spread, both the wood and bark gradually decaying. Very rarely is it in a dry state, and it has been my almost daily business to note when it bleeds the most freely, and it is certainly not after heavy rains, but rather when the atmosphere is moist, or what we usually term good "growing" weather. The clearer the weather, whether during the winter or summer months, the less bleeding is to be observed. Whether this is owing to a greater evaporation from the leaves, or whether the much greater loss of sap during dull moist weather is due to the latter being more sap-attracting, I am unable to say. I am inclined to the latter theory, and believe the maintenance of a drier atmosphere (not necessarily with a lower temperature), will materially check bleeding in Vines. If the condition of the atmosphere does not affect the bleeding, how is it they (the Holly and Vines) vary so remarkably, one day bleeding profusely, the next day perhaps not at all?—W. IGGULDEN.

My first notes on this subject were plain, and I think the way "Justitia" asks for proof is unjustifiable. He has re-read his remarks and again fails to see that I used only his own words. The question why some Vines bleed and others do not in one house can be answered in many ways if all the Vines receive the same treatment and are of different varieties. Again, if all are of one variety they often differ in character.

The ground differs in quality and roots work differently, and there is a marked difference in the bunches or berries. Strong healthy Vines bleed because they are full of sap and the roots working in moisture. Weak Vines bleed from their inability to appropriate the excess of moisture.

Indiscriminate pruning is said to be the cause of bleeding in large and mixed vineries, as all the Vines are not in a fit state at one time. If the Vines have all perfected their fruit and this has been cut, the foliage having all fallen, no mistake can be made if all be done at once. The evil is what I stated, but certainly if no pruning be done no bleeding will occur. Vines bleed whether pruned early or late, and in many cases when the buds are quite dormant. Pruning is thus an evil; but not to prune would be a much greater evil.

To show "Justitia" and "Non-Believer" that I can stop bleeding at will, I offer to amputate a rod of any Vine at any stage of growth, and to heal the wound, and consequently stop the bleeding, in two applications with a simple substance (powdered alum), a trial of which I communicated to this Journal (page 195, vol. vi., March 8th, 1883), and it was copied into many other papers.

If "Non-Believer" and "Justitia" visit me there will be no puzzle nor alarm. I cannot see where the former borrows the information that I blame your contributors for my own folly. I gained a practical lesson, and that is something. If a crop was lost on the young Vines, the old ones seem to respond to make up for the loss. A few persons around here have come to see no Grapes, and were sadly disappointed, as such ought to be. Men should read more carefully, think more, be civil, and laugh less at others' misfortunes. I can show a last year's cane from a spur that carried a large bunch of Grapes last year, with fourteen bunches now growing, some being over 13 inches long. The old rod, which has been carried up in three years, has now twenty-four—that is, thirty-eight bunches altogether, on the shoot roof. They cost about 12s. a year for coal, so your readers may judge. As soon as the buds begin swelling stable manure is used, renewed, or added to as needed. A little fire is employed at night if the weather be frosty, and when the Vines are in bloom up to the setting and thinning. Except in very damp dull weather this is all the artificial heat they receive, except that a little rubbish is burned to expel damp.—J. E. WAITING, *Grange-over-Sands*.

THE ORANGE-COLOURED CESTRUM.

UNDER the popular name of Bastard Jasmine a large number of plants belonging to the Potato family are known, the scientific title assigned to them being *Cestrum*, from the Greek name for Betony; but, like many other classical designations, its application to the Bastard Jasmine seems to be purely arbitrary. These plants are close allies of the *Habrothamnus*, a much-esteemed greenhouse flowering plant, the value of which is fully appreciated wherever flowers are in great demand for cutting. In the majority of the *Cestrum*s, however, the prevailing colours are very different from their neighbours—mostly orange, yellow, or white—and being as free in growth and flowering as the others, they are equally deserving of a place in collections. The Orange-coloured Bastard Jasmine, *C. aurantiacum*, of which an illustration is given in fig. 114, is a particular favourite with those who know it, though they are by no means so numerous as might be expected, considering that the plant has been an inmate of English gardens for more than forty years. It is one of those neglected plants which have gradually been pushed out of sight by the swarms of newcomers that have in recent years been obtained from all parts of the world. In some old gardens where plants have long been prized examples of these may occasionally be seen, but there they remain; for notwithstanding the enterprise of nurserymen in introducing plants from foreign countries, they appear to think any old plant, however meritorious it may be, beneath their notice. Doubtless the public themselves have had something to do with this—there is such a craving, almost a craze, for anything new; and the fact that a plant has been in cultivation for half a century appears to deprive it of half its value in the eyes of many purchasers.

Cestrum aurantiacum should certainly be rescued from its obscurity, for as a greenhouse plant it is invariably admired when seen laden with its abundant trusses of orange-coloured flowers. It is, moreover, most easily grown, needing no special attention beyond providing a well-drained compost of turfy loam and well-decayed manure. The growth is strong and quick, and if the plant is trained to the roof of a house or a pillar, either of which positions is suitable, it will require slight pruning occasionally to keep it in bounds and to remove the weak and straggling shoots.—W.

FRUIT TREES—SUMMER PRUNING.

THE time has now arrived for this important work to be commenced, and in the interests of those whose experience in fruit culture is limited a few remarks on the subject may be of some assistance. At the outset it must be stated that the importance of the work cannot well be over-estimated, as on it depends to a certain extent the well-doing of not only the current year's crops but of that

of the succeeding year; which being the case, it behoves most gardeners to exercise care and judgment, at the same time dispelling all pre-conceived ideas that summer pruning consists only of shortening back the young shoots of all trees alike, and at one and the same time.

Peaches and Nectarines take the first place amongst stone fruits, both in regard to their value and as being the earliest to push into growth. If they have been properly attended to up to the present the trees will have been disbudded twice or thrice by this time, so that all that is necessary for the rest of the season will simply be to nail in or tie, as the case may be, all young shoots required for next

Plums, both wall-trained and pyramidal, I always think should be left till the last week in June; and when the crop is light, as is the case this year, and the trees in good health, it is advisable not to cut back the shoots too closely—indeed two-thirds of their length will be quite sufficient, the rest to be removed at the winter pruning.

Pears may be treated in much the same way, and as this differs somewhat from the orthodox plan, or, rather, that which is considered to be so, perhaps I may be allowed briefly to state my reasons for advocating it. Given a strong healthy tree of Pear or Plum, wall-trained or pyramidal, cut back all young shoots near to their base not required for the extension of the tree, and what is the result?

Fig. 114.—CESTRUM AURANTIACUM.

year's bearing as they advanced in growth; and we would here recommend that a space of fully 3 inches should intervene between each one. This will insure greater certainty of ripening the wood, and at the same time allow of sufficient room for the full development of the leaves, thereby producing strong and plump fruit buds for another season. Vigorous young shoots will frequently push lateral growths, which must never be allowed to extend, but be pinched back to the first leaf—i.e., on old and fully established trees; but with younger ones the case is entirely different, for then the main object in view is to allow them to fill their allotted space in the shortest possible time.

Apricots next demand attention, and all that is required to be done to these is merely to cut back all breastwood to three or four leaves, and to nail-in young shoots to fill up vacant spaces which have been created by older branches dying.

Simply this, that in nine cases out of ten many of the buds which should go to form flowering ones for the succeeding year will be forced into premature growth shortly after being subjected to this close cutting-back process; whereas, if they had only had two-thirds or thereabouts of their length cut off, the contrary would have been the case. Apples grown on the restriction system can also be treated in this way.

We now come to small fruits, but of these there are only two kinds requiring our notice—viz., Gooseberries and Currants, and of only red and white varieties, whilst of the first named only those trained to walls. Anyone who has not hitherto practised summer pruning as here advocated for Currants and Gooseberries would, I feel sure, after a first trial adopt the plan. The young shoots are cut back about the second or third week in June to within four or five leaves of their base, and it only remains to be said that you will be rewarded

by larger fruit and more of it than would be the case if they were treated only to the customary winter pruning.—H. J. H.

HISTORICAL JOTTINGS ON VEGETABLES.

THE CARROT.

A GLANCE at the history of the Carrot shows us the circumstance, noticeable in connection with other well-known vegetables, that its annals present a dark space, falling during the period when civilisation declined throughout Europe, after the downfall of the Roman empire. We find the Carrot is mentioned by several authors writing early in the Christian era, and then we have a long interval, until the Carrot reappears in books belonging to the reign of Queen Elizabeth. It is unlikely that the plant ever went out of cultivation, but where it was grown, and by whom chiefly, we do not know. There is no doubt, however, that the monks of the middle and dark ages grew many fruits and vegetables in their gardens with which the world generally had no acquaintance, and they have at least a title to be called the friends of horticulture, or its preservers, whatever may be said against their teaching and their morals.

The Carrot (*Daucus Carota*) is one of the plants in that rather extensive order, the Umbelliferae, which embraces a singular variety of species—some most wholesome, some as dangerously poisonous. It occurs wild in various parts of Britain, seemingly having a preference for chalky ground. When in bloom, owing to the shortness of the central stalks in the mass of umbels, there is a hollow in the centre of the flower head which has been compared to the nest of a bird, and within this is a crimson flower, the others surrounding it being whitish. A less common species (*D. maritima*), found upon the Cornish cliffs, has no crimson flowers, and leaves that are thicker, also less finely divided. In these wild plants is perceivable a tap-shaped root, which is white, but tough, and various methods have been tried in vain for centuries past, with the object of changing or "educating" our native species. Varieties have indeed been produced by the culture of the wild Carrot for generations, and large roots—white, yellow, or red—grown; but these had not the flavour of the garden Carrot. Yet that is really no distinct species; it is considered to have been developed from *D. Carota*, through influences of soil, climate, or culture, and some conjecture the early home of the Carrot was the Isle of Candia; at all events, good evidence points to the vicinity of Greece. Even in the days of Gerard people called the plant the "Candie Carrot," prompted to this possibly by Pliny's remark that the best plants were grown in Candia, or in Achaia he adds. Before his time Theophrastus had referred to the culture of the Carrot in Areadia, and he also commended the Spartan Carrots, which may have been a customary item in those vegetable broths that delighted and invigorated the hardy Greeks of that nationality. By the Romans the Carrot was cultivated during the Empire, introduced from Greece, and they again probably took this plant to Gaul, to Germany, if not also to Britain. Gerard remarks that he had been told the cultivated Carrot was found growing apparently wild upon mountains in Switzerland and Germany. By the Greek growers the fact was noted that the Carrot thrives in dry moderately rich soil, but several of the old physicians who write upon it do not always clearly separate the Carrot from the Parsnip in their comments upon the good qualities of these vegetables, for both were known to the ancients; and the generic name of the Carrot is supposed to be derived from a classical word alluding to the warmth of the plant; the specific one, however, is obviously compounded from the Keltic *car*, or "red," expressive of the usual colour of the root. We glean few particulars concerning the modes of cooking Carrots in the Roman days of luxury. It may be that the fastidious rejected the inner and fibrous part of the root, eating only the dark and more pulpy exterior.

The Carrot was certainly re-introduced to England by one or more parties of those Flemings, who, flying from persecution at home, found a welcome in these shores between 1580 and 1590. Most of them landed in Kent (though some probably arrived in Essex or Suffolk), and, bringing with them these and other plants, they began to cultivate them upon such small plots of ground as they could acquire. Such additions to the then scanty stock of English vegetables were heartily welcomed, especially in London, and by degrees the Flemings worked nearer to the metropolis, to form market gardens on a style of their own. One novel use to which the leaves of the Carrot were put is mentioned by Parkinson. The ladies of the Court during the reigns of James and Charles I. occasionally employed them as an ornament for their head-dresses. Gerard does not tell us whether he grew Carrots in his city garden. His praise of the vegetable is rather

cautious. The roots he considered to be moderately nourishing, and suitable to accompany fat meat.

When suburban London did not exhibit, as now, a network of streets and terraces, but was prolific in market gardens and nurseries, surrounding here and there a village or hamlet, some little space was allotted to the Carrot, though it was not a favourite plant with those cultivators who endeavoured to have a quick succession of crops; hence a good part of the supply of Carrots required by the metropolis came from a distance, and railway facilities widened still more the area that contributes vegetables to its hungry millions. For their main crops the market gardeners of the eighteenth century relied upon what they called the Orange Carrot, which produced roots both long and large. This crop they sowed in February generally, and Abercrombie, Mawe, and others insist much upon the importance of having the ground dug very thoroughly with the spade beforehand, and also that the Carrot should not be grown near the shade of trees if that could be avoided. They seem to have supposed the best Carrots were raised by sowing them in beds 4 or 5 feet wide, with "alleys" dividing these from each other. We have some mention made of the Horn Carrot in the reign of George III., but until a comparatively recent date gardeners paid little attention to the culture of varieties of this vegetable; and the Carrot came but slowly into use here as a food for animals, being grown for that purpose on the continent long previously, in Belgium especially.

The clever but eccentric Arthur Young, however, in the course of his peregrinations discovered that Carrots were cultivated freely on sandy fields in East Suffolk, and published the fact with his comments thereon. An impetus was also given to the progress of this vegetable in the esteem of farmers by some statements put forth through the medium of the Society of Arts in 1765. Then Mr. Billing, a Norfolk farmer, informed the world that he had raised from 20 acres 500 loads of Carrots in one season, which proved of as much utility as 1000 loads of Turnips or 300 loads of hay. Other northern farmers began to follow in his footsteps, and the value of the Carrot as a winter food for cattle was recognised. The roots appear to have been first given to horses by breeders in the way of medicine rather than food. A very marked effect was produced upon the wind where horses suffered from shortness of breath, and others suggested eventually the vegetable would prove a good food for horses mixed with Oats. Then Carrots were tried with sheep and pigs, the result being satisfactory, and the crop on the whole is not found to be prejudicially affected by the variableness of our climate. Probably at this time between 20,000 and 21,000 acres are devoted to the culture of the Carrot in the United Kingdom.

Amongst the ancients there prevailed a belief that the Carrot, more particularly its seed, was a cure for stings and bites, used both internally and externally, and a few physicians of modern days have recommended Carrots to be given as a part of the diet of consumptives where they can be digested. Having some antiseptic qualities, a poultice of this root is good for several kinds of malignant skin diseases. There appears to be some special aromatic principle contained in the Carrot, but the bulk of the root is starch and sugar with a little albumen.—J. R. S. C.

GROWING PLANTS IN MOSS.

CAPT. HALFORD THOMPSON recently exhibited at the Royal Botanic and Crystal Palace Shows some boxes and baskets filled with plants grown in moss which attracted some attention. A number of plants were employed, the majority of which were healthy and growing strongly, though the system certainly seemed to suit the foliage plants better than those grown for their flowers, as might be expected, for a loose rooting material is generally more conducive of rapid foliage growth than the production of flowers. Possibly this disadvantage may be overcome, and there are some obvious conveniences in using the moss. In a small pamphlet by Capt. Thompson, his method and its uses are thus described—

"Attention was called two years ago to the possibility of growing plants in moss, without any earth at all. A Frenchman of the name of Dumesnil claimed to be able to do so with the aid of some 'fertilising moss' that he had patented. I made several experiments with this moss, but though in some instances they were successful, I found that it was open to very great objections, and was by no means certain in its results; moreover, the fact that this 'fertilising moss' must on no account be allowed to touch the roots of the plant was a great source of danger, and precluded its being used by anyone who was not a skilled gardener. Mons. Dumesnil told us that if his moss was allowed to touch the roots the plant would die, and my experiments proved that he was correct. The method he adopted was to place a layer of his patent moss above and below, the plant itself being in ordinary moss; the basket was, in fact, planted 'sandwich fashion.' As I have already said, this required skill, and besides this it frightened people to be told that the compound was so dangerous.

"Having found from my experiments with Mons. Dumesnil's 'fertilising moss' that it was quite possible to grow plants without any earth at all, I set to work to endeavour to impregnate ordinary moss with some fertilising substance that would enable plants to be grown in it without all the precautions necessary in using Mons. Dumesnil's patent moss. I think I may say that I have perfectly succeeded. Plants in full bloom can be taken out of the ground or out of the pots, and after all the earth has been carefully washed off, are planted in moss which has been previously prepared with my fertilising fibre. They never even flag, but grow more luxuriantly than in soil. I may be asked that, granting the possibility of growing plants without earth, what advantages are gained? In answer to this, I would point out the extreme lightness of the baskets I am showing, and the extraordinary manner in which I have been able to mix plants in the same basket of utterly different characteristics, and requiring utterly different treatment when grown in earth. In one basket, 2 feet 9 inches by 2 feet 3 inches, I have the following plants, all in thoroughly healthy conditions, viz.:—Anthuriums, Franciscea, Vitis variegata, and Rhyncospermum, while the whole of the basket is covered with Selaginella. In another basket I have tricolor Pelargoniums, perfectly hardy outdoor plants, growing round the outside, with a Caladium growing in the centre. By this means we are enabled to get a mass of different colours beautifully blended together, and all in a basket that can be easily lifted about by one person without assistance.

"In addition to the advantage thus gained of extreme portability, and of blending different colours together, there is another point of great importance to invalids, and even to persons in sound health who like to have flowering plants in their sitting-rooms. Such plants when grown in earth always have more or less a sour earthy smell, which is most unwholesome. This is entirely absent from plants grown in moss. If you want to water them, too, all you have to do is to carry them outside (a very different thing to carrying out a number of heavy flower pots), water them, let them drain, and bring them back.

"For 'hanging baskets' the system of growing in moss will be invaluable, and I may add that it will open a new era for the greatly increasing method of 'window gardening,' now employed in London by many who formerly had no chance of seeing flowers at all.

"Now, as to the way to use my moss, my method is so simple that it hardly requires any description:—Take the plants you wish to put into the basket, carefully wash off all earth from the roots with tepid water, taking care not to injure the roots in so doing, then plant them in the ordinary way in the moss, which should be previously well wetted; if possible, keep the basket in a warm place free from draught for three or four days. The plants can, if wished, be transplanted from earth when in full bloom; they will not feel the check. After two months the upper layer of moss should be removed and a similar quantity of my moss put in its place. If Selaginella or Variegated Moss are grown on the surface of the moss, these should be carefully removed first and replaced after the moss has been changed. The baskets do not require watering oftener than plants grown in earth do. The weight of the baskets will show if they want water."

VINE GROWTH.

"THINKER'S" "thoughts" on this subject are inaccurate. "A Kitchen Gardener" spoke of the "out-of-date" system of cutting Vines down to within "2 or 3 feet from the bottom," which was Mr. Pearson's plan as recorded in his book, and "Kitchen Gardener" recommended instead "rods 10 and 12 feet long the first year," which is the new plan. If it was hypercritical to distinguish between the two systems "Thinker" must apply that term to "Kitchen Gardener," whom I only corrected in reference to the origination of the practice. "Thinker," however, misapplies the word in this case; it can hardly be hypercritical to distinguish between a system of culture which gives a houseful of Grapes before the Vines "are well over their first birthday," as "A Kitchen Gardener" puts it, and another system which takes several years to accomplish the same result; and those who have discussed the subject previously in the Journal and elsewhere seem to think so. What Mr. Pearson would have done or said had he "been alive" I do not know, but what he did do and write when he was alive was quite contrary to "Thinker's" "presumptions" now; and the way to write history truly is to record what people did and said, and judge them thereby, and not to attribute suppositious acts to them to suit our own present fancy. It is quite possible "Thinker" may have seen long rods left the first year thirty years ago, but he knows it was far from the rule in practice to do so; and those who come forward with such far-back testimony now are like Dr. Johnson's friends, who "encumbered him with their help when he no longer needed it."—NON-BELIEVER.

THE OPHIOGLOSSUMS.

THIS genus of plants is closely allied to the Ferns, and many of the species have claims to cultivation. They are a class of plants quite distinct in appearance, and, like the Platyceriums, are quaintly ornamental. The family has a wide geographical range, one species being found in British meadows, and others in New Holland, Portugal, Japan, and the West Indies. The genus is named from *ophis*, a serpent, and *glossa*, a tongue, and hence the name of Adder's-tongue, which is the popular name of the familiar English species. One of the most curious of the family is

O. pendulum, which is a native of Madagascar, where it is found growing on forest trees, its fronds hanging from the branches to a length of several feet. It is often found growing with *Platycerium grande*, and requires much the same mode of cultivation as that quaint plant. It is at home on the rocks of the tropical fernery, and will grow freely in a spongy mass of peaty soil.

O. palmatum (fig. 115) is one of the best of the species. It is somewhat rare, yet is not difficult to cultivate. It does not require a great depth of soil, but will luxuriate in a rough open composition of sphagnum, turfy peat,

Fig. 115.—*Ophioglossum palmatum*.

and charcoal, if a place is afforded it in a well-heated structure, and a copious supply of water is given in the growing season. This species when well grown is a distinct and ornamental plant, and one that is well worthy of all the care that can be bestowed in its cultivation. Plants may be increased by divisions of the roots or by seeds, but in either case the process is a slow one, and for a supply of these plants we must rely mainly on importations. The Portuguese species *O. lusitanicum*, and the British species *O. vulgatum*, are the most common, and have a place in most large collections of plants.

Several pretty species are found in India as well as other tropical regions, and amongst these may be mentioned *O. fibrosum*, with delicate little closely veined fronds, and *O. reticulatum*, with a similarly fine network of veins upon the fronds. It is surprising how widely distributed these Ferns are. For instance, the common *O. vulgatum* is not only found throughout Europe, but it extends into Africa, Japan, India, Australia

New Zealand, and the Sandwich Islands. Some of the others are equally common to the tropics of both the Old and New Worlds.—X.

COMING FLOWER SHOWS.

EXHIBITIONS are as numerous as ever, the following being those for June, July, August, and September, of which we have received any notification at present :—

- June 19th.—York Floral Fête. Sale (three days).
 „ 24th.—Royal Horticultural Society, Fruit and Floral Committees ; Fruit and Vegetable Show, South Kensington.
 „ 25th.—Croydon (Roses). Leeds (three days). Tooting (two days).
 „ 26th.—Richmond. Canterbury (Roses).
 „ 28th.—West Kent. Camden Park, Chislehurst. Reigate (Roses).
 July 1st.—Edinburgh International Forestry Exhibition. National Rose Society, South Kensington. Stoke Bishop.
 „ 2nd.—Royal Botanic Society's Evening Fête. Hull (three days). Wimbledon. Cardiff.
 „ 3rd.—Bury St. Edmunds. Winchester (two days). Bath (Roses). Chiswick. Farnham (Roses).
 „ 4th.—Sutton (Roses). Tunbridge Wells.
 „ 5th.—Crystal Palace (Roses).
 „ 7th.—Brockham (Roses).
 „ 8th.—Royal Horticultural Society, Fruit and Floral Committees ; Promenade Show.
 „ 9th.—Edinburgh (two days). Salisbury (Roses). Lee (two days).
 „ 10th.—Oxford (Roses).
 „ 14th.—Wolverhampton (three days).
 „ 16th.—Bedford.
 „ 17th.—Carlisle (two days). Warkworth (Roses). Newport.
 „ 19th.—Manchester (Roses).
 „ 22nd.—Royal Horticultural Society, Fruit and Floral Committees ; Fruit and Vegetable Show ; Carnation and Picotee Show.
 „ 23rd.—Newcastle-on-Tyne (three days). Feltham.
 „ 24th.—Sheffield (two days).
 „ 30th.—Warwick.
 August 2nd.—Liverpool (two days).
 „ 12th.—Royal Horticultural Society, Fruit and Floral Committees ; Cottagers' Show.
 „ 14th.—Maidenhead.
 „ 20th.—Shrewsbury (two days).
 „ 21st.—Reading.
 „ 26th.—Royal Horticultural Society, Fruit and Floral Committees ; Fruit and Vegetable Show. Banbury.
 September 2nd.—Stratford-on-Avon (two days).
 „ 3rd.—Glasgow. Bath (two days).
 „ 5th.—Crystal Palace Fruit and Dahlias (two days).
 „ 9th.—Royal Horticultural Society, Fruit and Floral Committees.
 „ 11th.—Bury St. Edmunds (two days). Dundee International (three days).
 „ 17th.—Edinburgh (two days).
 „ 25th.—Royal Horticultural Society, Fruit and Floral Committees ; Fruit and Vegetable Show.

CACTACEOUS PLANTS.

(Continued from page 422.)

CEREUS GRANDIFLORUS MAYNARDI.—This magnificent hybrid is unfortunately now rather scarce, yet its beauty and distinctness entitle it to prominent attention. In 1837 Mr. H. Kenny, gardener to Viscount Maynard, Easton Lodge, Dunmow, Essex, crossed *C. speciosissimus* with pollen from *C. grandiflorus*, and, the fertilisation proving successful, seeds were obtained which produced the plant under notice. This combined the characters of the parents in a striking manner, the habit of growth and form of the flowers of *C. grandiflorus*, with the addition of the rich colour of *C. speciosissimus*, rendering it invaluable. The flowers are 9 to 11 inches in diameter, and 7 to 9 inches long, the petals more cupped than in the ordinary *C. grandiflorus*; they are rich red with a tinge of orange, and usually last for two or three days, opening every evening. At its original home, Easton Lodge, now the residence of Lord Brooke, the plant had been quite lost, until recently, by the generosity of Mr. Major of Croydon, a specimen was furnished to the gardener Mr. H. Lister.

C. SPECIOSISSIMUS.—Though stronger in growth than the majority of the trailing species, this may be considered in that group, as it is more frequently grown trained to a wall, rafter, or trellis than in any other way. With very slight support it will assume an erect habit, but the upper parts of the branches then hang downwards, indicating the natural habit of the plant. It is a superb plant, and when in flower it cannot be rivalled in brilliancy by any other plant grown under glass. Large specimens are frequently seen in old gardens, but one of the most notable that I have seen is at Orsett Hall, Romford, the residence of Capt. Wingfield Baker. This has about thirty stems, each 6 to 8 feet high, which have been produced by repeatedly cutting down the main stem, and during April or May there have frequently been from sixty to eighty buds and flowers upon the plant at one time, sometimes twenty being fully expanded. This plant is in a large pot, and has not been disturbed for many years. The gardener, Mr. R. Castle, finds that all the assistance it requires is a good supply of water at the time of flowering, with a little weak liquid manure occasionally. It is, however, a fast-growing species, and is benefited by a rather richer compost than that usually afforded such plants, a small proportion of old manure being incorporated with the loam and sand employed.

The stems often assume a reddish hue, are about 1½ to 2 inches in diameter, with three to five rather deep ridges, furnished with prominent clusters of spines in dense tufts of white wool-like substance. The flowers vary greatly in tint, usually presenting a beautiful combination of scarlet and purplish crimson, the petals being quite glossy and shining in sunlight. They vary in size from 6 to 8 inches, the petals expanding fully with abundant stamens. When cut and placed in water they will last three or four days, retaining all their brilliancy of colour for that period. The fruits are green, ovate in form, 1 to 1½ inch long, with a pleasantly flavoured subacid pulp, somewhat suggestive of nearly ripe Gooseberries.

The species was originally introduced from Mexico to Madrid, and was thence sent to Paris by the Comte de Salm. It passed to this country, and

is believed to have first flowered in the collection of the Comtesse de Vandes about 1820, when it was figured in the "Botanical Register" (t. 486).

Numberless varieties have been raised from *C. speciosissimus*, as it seeds freely and crosses readily with other species. Many years ago Mr. Donald Beaton raised scores of seedlings from crosses between that and *C. flagelliformis*, and has stated that he never found a barren seedling. Mr. Pressley, gardener to W. Boyd, Esq., Plaistow, also raised some seedlings about 1832, some of which were exhibited, one named *lateritius* being described as of a very beautiful scarlet tint. Much attention was given to these plants about that time, for Sir Edmund Antrobus is said to have exhibited specimens with from 200 to 300 flowers each, which were as greatly admired then as large specimen Orchids are now. Hybrids between this *Cereus* and some of the *Phyllocactus* have also been obtained, but these will be referred to under the latter genus.

C. SPECIOSISSIMUS HYBRIDUS [MALLISON].—A beautiful hybrid from *C. speciosissimus* (the seed parent) and *C. flagelliformis*, which is deservedly a great favourite in many gardens. It was raised over fifty years ago by Mr. Mallison, gardener to Sir Samuel Scott, and is curiously intermediate between the parents, resembling the seed parent in the size, colour, and form of the flowers, and the other in habit, though with rather stronger stems. It has bright rosy crimson flowers 4 to 6 inches in diameter, very freely produced, and most handsome when the stems are trained to a rafter and then allowed to hang over a path. It is grown in this way at Kew, where a fine specimen is grafted upon a stem of *C. MacDonaldiae*. It requires a rather warm position in a stove.

C. MACDONALDIE, Hocker.—A handsome slender-stemmed species, which ought to be grown much more generally than it is at present, for it is one of the finest of the night-flowering Cactæ. It resembles *C. grandiflorus* in the size and appearance of the flowers, which are frequently 12 to 14 inches in diameter, with creamy white lanceolate petals with an outer fringe of narrow yellow sepals. The growth is, however, different, the surface of the stem being covered with irregular tubercles, not distinctly ridged as in most other species; it is slender, usually half to 1 inch in diameter, and trailing. A fine specimen is grown in the Cromwell House collection, trained over the wire arch shown in fig. 93, p. 405, and this plant has produced flowers 14 inches in diameter. Mr. W. Wright, the gardener in charge of this collection, has crossed *C. MacDonaldiae* with pollen from *C. speciosissimus*, which may be expected to yield an interesting and beautiful progeny. The species was introduced from Honduras to Kew by Mrs. General MacDonald, and first flowered in the Royal Gardens in 1851.

C. FLAGELLIFORMIS, Haworth.—Under the popular names of Whip-cord and Rat's-tail Cactus this plant is well known, and probably is the most generally grown of all the *Cereus*. It is one of the oldest-known in England, having been introduced in 1690 by the Earl of Portland, the same year as *C. triangularis* made its appearance here. The plant was cultivated by Miller, and was included in the Kew collection in Aiton's time. In reference to its habit and the number of ridges on the stem it was named by some of the old writers *Cactus repens decemangularis*, and amongst other still older titles bestowed upon it was *Ficoides americanum*, in reference to its native country, Peru, and contiguous districts of South America. The stems are very slender, about half an inch in diameter, and they grow to the length of 4 or 6 feet, being of pendulous habit. At Kew there is a fine example grafted upon a stem of *C. rostratus* 6 feet high, which has a dense cluster of branches, about sixty, each 4 or 5 feet long. When flowering this has a most striking effect, the bright rosy-coloured flowers, which are produced in spring and early summer, being extremely attractive. Owing to its very pendulous habit this species is generally seen to better advantage grafted on a stem of the columnar *Cereus*, upon any of which it seems quite at home. When on its own roots it appears to succeed best in a loamy compost, porous, but heavier than is usually given to Cactæ.

Many other trailing *Cereus* could be named, such as *C. Napoleonis*, *C. rostratus*, *C. Lemoinei*, *C. Karstenii*, *C. nycticallis*, *C. Cavendishi*, *C. serpentinus*, and *C. colubrinus*, but they are most rare, and as regards their floral attractions, those already described are preferable.—L. C.

NOTES FROM BOURNEMOUTH.

PERHAPS a few notes respecting the floral and arboreal beauty, situation, and surroundings of this far-famed health-giving Hampshire seaside town may prove interesting to those of your readers who may not have had an opportunity of visiting it.

Bournemouth is situate on the slopes and tableland east and west of a valley about a mile and a half long, and from 150 yards to 200 yards wide in its greater length, in the midst of Pine trees and a variety of flowering and ornamental shrubs. Except those in Southbourne Terrace and the Landsdowne Road, in which the several banks, town hall, theatre, arcade, &c., together with the numerous fashionable shops, are situate, the houses, for the most part, are detached villas, nestling in the privacy of their own well-kept grounds. Some distance from the well-made and capitally kept public roads and footpaths, and between the latter and the former, on either side, is a row of Pine trees, which afford at all times an agreeable shade. These gardens, the owners of which seem to vie with each other in the possession of graceful trees and shrubs and floral masses of various colours, extend for miles, and for the last month, especially in those gardens in the neighbourhood of the Old Christchurch Road, the Laburnum, Scarlet Thorn, White Broom, L. lac, &c., have formed a very pleasing picture.

The Public Pleasure Gardens.—These are situated in the valley referred to above, which slopes gently from the neighbourhood of the west station of the Salisbury, Bournemouth, and Weymouth branch of the London and South-Western Railway in a southern direction to the handsome and substantially constructed iron pier. In the formation and planting of these extensive gardens taste and judgment have been exercised by the landscape gardener in turning to the best advantage the liberal assistance which Nature, in the undulated surface and surroundings of this once wild valley of Pinewood and Heather, freely offered to his art. Through these gardens flows, in a southern direction, a quiet stream or bourne, which,

winding under tunnels and ornamental bridges, passes into the sea beneath the pier. But insignificant as this brook may appear, the town of Bournemouth derives its name from it.

In the expanse of closely cut green sward between the two longitudinal walks and the stream are a few pairs of circular beds, bright with late spring-flowering plants and shrubs; the side borders between the roads and the long walks, which are connected by transversal ones and bridges at convenient distances from each other, being remarkably gay with the foliage and flowers of Rhododendrons, Flowering Currants (*Ribes sanguineum*), White Broom (*Cytisus albus*), Laburnums, &c. These borders, as well as the "Invalid's Walk," and the several shady walks leading therefrom among the Pine trees, which in the locality of the Royal Bath Hotel and pier, climb the slopes 200 or 300 yards eastward, having a groundwork of Rhododendrons and a boundary of Evergreen Oak (*Quercus Ilex*), The Strawberry Tree (*Arbutus unedo*), &c., are all edged with Thrift (*Armeria maritima rubra*), and there being a couple of miles in length of it in the aggregate, it is very effective now, as it has been for several weeks past.

Coniferae are sparingly represented at the top end of the gardens, where being sheltered somewhat from the effects of the salt breeze, the trees are more luxuriant in growth than those in other parts of the garden. Indeed it is only in situations so sheltered that trees and shrubs, with one or two exceptions, flourish in Bournemouth, as evinced by the poor condition of the young Pine trees (*Pinus austriaca*), recently planted in the triangular piece of ground thus formed by the junction of the two principal walks at the pier entrance to the gardens. These are nearly all dead, and this can scarcely be wondered at, though by the erection of a hoarding of some kind until the trees had established themselves perhaps it might be avoided, as the position (the mouth of the valley, and within a hundred yards of the sea), is a very exposed one. Most of the outside rows of Pine trees along the cliffs have been killed by the force of the wind and wave, and salt combined. The most striking instance of destruction thus wrought is that which meets the eye at the south-western angle of the Pinewood above Earl Cairns' mansion on the East Cliff. Scores of these trees together, from 30 feet to 40 feet high each, are quite destitute of foliage. Two good seaside shrubs, however, are the green-leaved *Enonymus*, which within a few dozen yards of the pierhead on the West Cliff, is nearly buried in drift sand, and the double-flowered Gorse; the latter being in grand flower during the last few months on the East Cliff, about three-quarters of a mile from the pier. The same may be said of those occupying the enclosed space between the fence enclosing Landisfarne Gardens and the Gervis Road, where the bushes having become rather long and bare-stemmed, with the assistance of the switching hook and long crooks, Mr. Spong, Earl Cairns' energetic head gardener, very properly placed in a horizontal position last spring. I need scarcely add that the result of this judicious treatment a year or two hence will be a dwarf hedge well furnished from base to summit with foliage and flowers of the softest yellow imaginable. Great praise is due to the authorities of Bournemouth for the consideration which they have shown in reference to the accommodation and comfort of those visiting the gardens, roads, and cliffs, by fixing rustic and ornamental garden seats in sunny and shady nooks commanding pleasant views of the sea.

The most important private gardens in Bournemouth are Hume Towers, the residence of John Lellom, Esq., and which for the last fourteen years has been ably presided over by Mr. William Earp, an old Garston man; Landisfarne, Earl Cairns' garden; and the beautifully laid out grounds in connection with the Royal Bath Hotel, and in the planting and keeping of which, together with the evidence of skilful culture in the various vineries and plant houses and kitchen garden, the gardener, Mr. Hawks, is to be complimented.

I may be allowed to say by way of showing the rapid growth of Bournemouth, which now contains about twenty churches, that a pensioner bricklayer on this estate assisted in building the first house in this now celebrated "Mentone" of England.

My notes would be incomplete without a reference being made to Mr. E. White's floral establishment in the Holderness Road. It is a summer and winter garden, a young Crystal Palace, and in the pretty, though small, grounds in front of this huge combination of glass and iron are a couple of good specimens of the Chilean Pine (*Araucaria imbricata*). They are about 30 feet high, the stems being 3 feet in circumference at that distance from the ground, and are furnished with healthy branches. Within a short distance of these are also two good specimens of *Cryptomeria japonica elegans*. Neither must I omit to mention the Rhododendrons in Boscombe Chine on the East Cliff, and the beautiful trees and shrubs in the still more beautiful burial ground on the steep slopes to the rear of St. Peter's Church, where on either side the broad walk leading in the direction of the vicarage are thirty-two of the finest and most uniform pyramid oval-shaped bushes of *Arbor Vitæ* which I have seen for a long time. They are about 12 feet high and 6 or 7 feet through, and are the picture of health.—H. W. WARD.

THE TIMBERS OF NEW SOUTH WALES.—It is a common error to assume that New South Wales is deficient in timber suitable for industrial purposes; on the contrary, the Colony is rich in different kinds of wood of the most valuable character, among which the Red Cedar occupies a prominent place. It is one of the most useful descriptions known, being very durable, easily worked, and easily adapted for furniture and all kinds of ornamental indoor work. In some parts of the Colony there are large Cedar forests, in which the trees are found growing to a very

great size, one block recently cut and shipped from the Richmond River to South Australia being valued at £600. The whole of the interior woodwork of some of the Government offices in Sydney is constructed from this wood, which has the appearance of rich, light-coloured mahogany. Several kinds of Gum Tree are largely used in colonial manufacturing industries. Among these is the Red Gum, the timber of which is highly valued for strength and durability, especially for piles and posts in damp ground. It is employed largely for ship-building, railway sleepers, bridges, wharves, and numerous other purposes. The Spotted Gum is used in a similar manner, also for naves of wheels, cart and buggy shafts, cubes for street-paving, staves, shingles, and general building purposes, where a strong, close-grained, and durable timber is required. Another wood of the same character is the Red Ironbark, to which may be added the Grey Ironbark, both of which are abundant in many parts of the Colony.

GRAPE-THINNING.

A FEW words in answer to "J. J.'s" criticisms (page 439), of my remarks on the above subject. I will take his last objection first, as it is the only one of importance. "J. J." states, "'T. A. B.' also says, 'The berries should not touch one another.'" What I did say is, "Allowing the berries to touch each other during the stoning period is a sure way of producing scald." "J. J." says, "Scalding takes place when the berries are stoning," which is true, and for that reason I advise lifting up the shoulders to prevent the various parts of the bunches resting upon each other, as I find that where the berries are in contact the moisture is sure to remain too long to be safe. All of us are not provided with efficient heating and ventilating apparatus. My boiler is so inadequate to its work, and the ventilation so badly arranged that I am not able to leave "a crack" of air all night unless the weather is very mild, if I was there would be less danger. I am aware that allowing the berries to touch each other is not the sole cause of scalding, but unless the ventilation is very carefully attended to it may be one cause. My bunches are not like some of the monsters "J. J." speaks about; they are only moderately large, ranging perhaps from three-fourths of a pound to 3½ or perhaps 4 lbs. On some of them the greater diameter is across the shoulders, and I fail to see how tying could be dispensed with. Tying may be and frequently is overdone, and unless this is altered in time the bunch will be spoiled, but that is no reason for dispensing with it altogether. The piece of twisted matting recommended for removing the bunch I consider more convenient than a piece of stick with V-shaped ends. I have never seen a really good bunch at a show where the shoulders had not been tied, but in many cases I have seen the shoulders carefully held in position by means of a small pad of cotton wool placed under them.—T. A. B.

ROYAL BOTANIC SOCIETY.

JUNE 18TH.

THOUGH less brilliant than the preceding Show of this Society, that held on Wednesday last was a large and beautiful one. There was a slight want of colour in the large tent, but no doubt the dull weather contributed greatly to this effect. The total number of exhibits was very large, and in the fruit classes especially the entries were numerous.

ORCHIDS.—A fine display of Orchids was again provided in the large tent, the plants being large and profusely flowered. The best amateur twelve specimens were from Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, who had beautiful examples of *Dendrobium Bensoniæ*, *Masdevallia rosea*, *Cattleya Mossiæ* Southgatei, *Odontoglossum vexillarium*, richly coloured, *Cattleya Warneri*, *Dendrobium suavisimum* in grand condition, and several others. Mr. Catt, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, was a close second, having handsome specimens of *Vanda teres*, *Lælia purpurata*, *Dendrobium Bensoniæ*, and *Masdevallia Harryana*. Mr. F. J. Hill, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, secured the third prize with healthy well-flowered plants. In the nurserymen's class for the same number of specimens Mr. H. James, Norwood, was first with very large *Cattleya Mossiæ*, *Aerides odoratum*, *Odontoglossum cordatum aureum* with six spikes, and *Epidendrum vitellinum*. Mr. J. Cypher, Cheltenham, followed, showing *Dendrobium Bensoniæ* very well; *Brassavola Digbyana*, *Cypripedium nivicum*, and *Dendrobium infundibuliforme*. Messrs. T. Jackson & Son, Kingston, were third with smaller plants.

The leading prize in the amateurs' class for six plants was gained by Mr. Child, gardener to J. Bell, Esq., Garbrand Hall, Ewell, with very handsome specimens, *Cypripedium Stonei* major having four spikes of eighteen flowers; *Aerides Lobbi* with two panicles of three and four branches each and one long spike; *Vanda suavis* with three spikes, *Oncidium ampliatum majus*, *Aerides Fieldingi floribundum*, and *Cypripedium barbatum superbum*. Mr. Salter was second with smaller but well-grown plants. Messrs. Jackson took the lead with six in the nurserymen's class, showing several *Cattleyas*, *Dendrobiums*, and *Cypripediums* in fine condition; *Dendrobium thyrsoiflorum* with eight fine spikes was especially notable. Mr. H. James was second with a good assortment, including a very large *Anguloa Clowesi* with eight large flowers.

Mr. H. James was the only exhibitor of twelve *Nepenthes*, securing first honours with a collection of large specimens similar to what have been before described.

PELARGONIUMS.—Two beautiful corner groups were formed of these near the entrance to the tent, especially fine being the six Fancy specimens from Mr. C. Turner, Slough, who was first in that class. These were profusely flowered, *Delicatum*, Mrs. Pope, The Shah, and Nelly Fordham being charming. Mr. Turner's best six Show varieties were nearly as good, *Comtesse de Choiseul* being in the grandest condition. *Ritualist*, *Illuminator*, and *Victory* were very fine. Mr. Cypher had the second place with six Show varieties, very neat and well-flowered plants. Mr. Wiggins,

gardener to W. Clay, Esq., Kingston, won premier honours in the amateurs' class for six Show varieties, a bright, handsome collection. Mr. F. J. Hill, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, followed with thinner but fairly good specimens. He was, however, an easy first with six Fancy varieties, even, fresh, and profusely flowered specimens, being followed by Mr. Wiggins with smaller examples. Mr. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, had six neat Zonal Pelargoniums, well flowered, being followed by Mr. Weston, gardener to D. Martineau, Esq., Clapham Park.

STOVE AND GREENHOUSE PLANTS.—Mr. J. Cypher was the principal exhibitor in the open class, taking the first place with twelve beautiful plants, including *Erica Cavendishiana*, *Ixora Williamsi*, *Allamanda Hendersoni*, and *Stephanotis floribunda* in superb form. The second honours were adjudged to Messrs. Jackson & Son, several of these plants being scarcely in their best condition. *Pimelea mirabilis*, a globular well-flowered specimen. Mr. H. James followed with small but fresh and neat specimens of *Heaths*, *Azaleas*, and *Statice*. Mr. J. Cypher staged the leading collection of six specimens in the nurserymen's class, most praiseworthy plants; *Ixora Fraseri* being loaded with flowers, *Erica depressa* in grand condition, and *Dipladenia amabilis* very handsome. Mr. J. F. Mould was second with small specimens. Mr. H. James was third, having a good *Erica Cavendishiana*. Mr. J. Child took the lead with six plants, including *Dracophyllum gracile*, *Erica depressa*, and *Aphelaxis macrantha purpurea*, very fine. Mr. Gibson, gardener to T. F. Burnaby Atkins, Esq., Halstead Place, Sevenoaks, was second with profusely flowered plants. Mr. Rann was third.

Messrs. J. Laing & Co., Forest Hill, had the only collection of twelve Tuberos Begonias, a choice selection of the leading varieties, distinguished by the great size and rich or soft colours of their flowers. Mr. Child was also first in the amateurs' class, with good plants and varieties. Mr. J. Tong, gardener to J. S. Law, Esq., South Lodge, Southgate, was second.

Fine-foliage plants.—Mr. H. James won the chief prize for six specimens, his best plants being *Theophrasta imperialis* and *Anthurium regale*. Mr. F. Mould, Pewsey, was second with smaller plants. Mr. C. Rann had the best six fine-foliage plants, the Palms and Crotons being very good. Mr. G. Wheeler was a good second, his *Corypha australis* being very fine; and Mr. R. Butler followed with large Palms and Crotons, the latter rather wanting in colour. The best six Palms were shown by Mr. Rann, his gigantic *Phoenix seychellarum* being very prominent and effective. Mr. James was second, his central specimen of *Areca lutescens* being of great size and in fine condition. Mr. R. Butler, gardener to H. H. Gibbs, Esq., St. Dunstan's Lodge, Regent's Park, was third with healthy plants.

An excellent collection of Ferns from Mr. Rann, gardener to J. Warren, Esq., Handcross Park, Crawley, gained him first honours in the class for six specimens, *Davallia Moreana* 7 or 8 feet in diameter, *Cyathea dealbata*, 10 feet high and as much in diameter across the head of fronds, with *Todea africana* of nearly equal size, were magnificent. Mr. J. Child secured the second place with similarly praiseworthy plants, as healthy and well grown as could be desired.

FRUIT.—There was a good display in the classes provided for fruits, and in some the competition was very keen.

Pine Apples.—For one Queen Pine Mr. F. Coomber, gardener to J. H. Rolls, Esq., M.P., The Hendre, Monmouth, was first with a beautiful even well-ripened fruit of about 6 lbs. weight. Mr. T. Hare, the Gardens, Wellingore, Grantham, followed with a well-developed specimen, and Mr. G. T. Miles, gardener to Lord Carrington, Wycombe Abbey, Bucks, was third with a fruit weighing 5½ lbs. There were five entries. For any variety not a Queen Mr. Muir, gardener to C. R. M. Talbot, Esq., M.P., Margam Park, Tarbach, was first with Charlotte Rothschild, weighing 6 lbs., in fine condition. Mr. G. T. Miles was second, and Mr. Bates, gardener to J. E. Meek, Esq., Poulett Lodge, Twickenham, third, both with Smooth Cayenne.

Melons.—A class was provided for two fruits, one green and the other scarlet-flesh. Of six competitors Mr. Chuck, gardener to C. S. A. Thellusen, Esq., Broadworth Hall, Doncaster, was first with High Cross Hybrid and Royal Ascot; Mr. Hollingworth, The Gardens, Woodseat, Uttoxeter, second with Trentham Favourite and Hero of Lockinge; Mr. C. Herrin, The Gardens, Chalfont Park, following with Victory of Chalfont and Blenheim Orange.

Grapes.—Considerable space was occupied by the entries in these classes; the black Grapes being generally of fair quality. For a basket of black Grapes Mr. Wildsmith, gardener to Viscount Eversley, Heckfield, was first with Black Hamburg, large in berry and bunch, and beautifully coloured. Mr. E. Adams, gardener to W. H. Trego, Esq., was second, and Mr. W. Fyfe, gardener to W. W. F. Dick, Esq., Thames Ditton House, third with the same variety. Five baskets of a white variety were staged. Mr. P. Feist, gardener to R. J. Ashton, Esq., Bishopsgate House, Staines, winning chief honours with Muscat of Alexandria, large in bunch and berry, but deficient in colour. Mr. Mowbray, gardener to the Earl of Leven and Melville, Fulmer, Slough, was second with Buckland Sweetwater well ripened; and Mr. Cakebread, gardener to Sir P. F. Rose, Bart., Raynes, Bucks, was third with Foster's Seedling of good size and fairly ripened.

In the class for three bunches of Black Hamburgs the competition was extremely keen, no less than thirteen exhibitors entering. Mr. Wildsmith won the first honours with three magnificent bunches, large in berry and splendidly coloured. These also secured the Veitch memorial medal and prize of £5 for the best three bunches of Grapes in the Show, a double honour of which Mr. Wildsmith may well be proud. Mr. W. Chuck was second with even beautifully coloured bunches, and Mr. Woodbridge, The Gardens, Syon House, was placed third with well ripened examples of good size. A similar prize was awarded to Mr. T. Coomber for bunches of good size.

For three bunches not Black Hamburgs, Mr. G. T. Miles was first with fine specimens of Gros Colman, large and grandly coloured. Mr. Loudon, gardener to T. Barnes, Esq., The Quinta, Chirk, was second with Madresfield Court of fair size, but wanting colour. Mr. Mowbray was third with Black Prince.

White Grapes were well represented in point of numbers. For three bunches of Muscat of Alexandria there were six competitors, Mr. Loudon gaining the chief place with good bunches, two of which were well coloured. Mr. Cakebread was second, and Mr. Feist third, both showing rather green examples. For three bunches of any other white Grapes Mr. Adams took the lead with Buckland Sweetwater in good condition. Mr. R. Grey, gar-

dener to Earl Stanhope, Chevening, Sevenoaks, was second with Foster's Seedling, large in bunch and berry; and Mr. Herrin was third with the same variety. There were ten entries. Peaches, Nectarines, Cherries, and Strawberries were not largely shown, the principal prizes being taken by Messrs. W. Bones, Hare, Kemp, Chuck, and Sharpe.

The Fruiterers' Company's prize of ten guineas for the best collection of fruits was gained by Mr. Wildsmith, who had Pine Apples, Grapes, Melons, Peaches, Nectarines, Strawberries, Figs, and Cherries, all in fine condition.

Cut flowers occupied considerable space in the long tent. Roses were well shown by Mr. Hollingworth, Turkey Court, Maidstone; Messrs. Paul and Son, Cheshunt; Mr. W. Robbins, gardener to E. Dyke Lee, Esq., Hartwell House, Aylesbury; and Mr. A. Gibson. The principal exhibitors of miscellaneous flowers were Mr. W. Balchin, Brighton; Mr. H. James, Mr. C. J. Salter, Mr. Gibson, and Mr. Weston. Mr. C. Turner, Mr. Little, and Mr. Clay showed the best stands of Pelargonium blooms. Several collections of wild flowers were also contributed.

The miscellaneous exhibits added materially to the effect of the show many handsome groups being displayed. Mr. Baxter, gardener to Sir Trevor Lawrence, exhibited a handsome group of Masdevallias, for which a silver medal was awarded. From Mr. B. S. Williams, Holloway, came an effective collection of Orchids and various greenhouse plants. Cattleyas were in great force, and a small silver-gilt medal was deservedly accorded to the group. Messrs. W. Cutbush & Son, Highgate, exhibited a group of greenhouse plants, including Azaleas, Stephanotis, Ericas, and others. A small silver medal was awarded. A magnificent group of Begonias from Messrs. John Laing & Co., Forest Hill, represented one of the finest features of the Show. It was a display of flowers of great size and variety of colour. A small silver-gilt medal was awarded. Messrs. J. Veitch & Son, Chelsea, had a collection of cut flowers, consisting of Irises, Brompton Stocks, Gladioli, Ixias, Antirrhinums, and others. The first-named were very fine and diversified and Gladiolus Colvilli alba was in excellent condition. A large bronze medal was awarded. The same firm sent a group of greenhouse plants, the Gloxinias being exceptionally good. This also was a fine collection, and a large silver medal was awarded. Mr. C. Turner, Slough, exhibited a fine collection of Pelargoniums amongst the other miscellaneous groups, and was awarded a large bronze medal. Mr. J. Burns, gardener to Mrs. Bond Cabbell, Cromer, exhibited six pots of scarlet Brompton Stocks of good colour. Messrs. Barr & Son, Covent Garden, were represented by a very large collection of cut flowers, amongst which Poppies, Irises, Gladioli, Lilliums, Pæonias, Ixias, and Pyrethrums were strikingly to the fore. A large bronze medal was awarded. Messrs. Hooper and Co., Covent Garden, sent an excellent collection of cut flowers, largely consisting of Pæonies and German Irises. It included many other popular hardy flowers, however, and a small silver medal was adjudged to it. Messrs. Paul & Son, Cheshunt, exhibited a very large collection of hardy plants, comprising Campanulas, Aquilegias, Pansies, Pæonies, Poppies, Geums, Irises, and numerous others. This was a really grand group, and attracted considerable attention and received a silver medal. Messrs. Kelway & Son, Langport, Somerset, also sent a miscellaneous collection of flowers, including Pyrethrums, Pæonies, and Amaryllises. A certificate was awarded. Mr. W. Chuck, gardener, Brodsworth Hall, Doncaster, showed a dozen cut blooms of Souvenir de la Malmaison Carnation in fair condition. The miscellaneous fruit exhibits were not very extensive. Four Queen Pine Apples were sent by Mr. Fry, gardener to L. J. Baker, Esq., Haydon Hall. A Melon from Mr. Chuck, and another from Mr. C. Herrin, gardener to J. N. Hibbert, Esq., Slough, were also exhibited. A dish of Lord Napier Nectarines were shown by Mr. Mundell, gardener to Lord Ebury, Rickmansworth, and of Bellegarde Peaches by Mr. Bones, Havering Park. Mr. Woodbridge, gardener, Syon House, Isleworth, was awarded a certificate for fruit of *Vanilla planifolia*. Mr. P. Feist, Bishopsgate House, Staines, showed three fair bunches of Muscat of Alexandria Grape.

KITCHEN GARDEN.

The Season and Vegetables.—In our district the season is one of the most favourable experienced for some years for all kinds of vegetables. There are many who think that a mild winter favours the production of insect pests, but so far these have been scarce and have done little damage. Indeed, they are far less destructive than they have been after the most severe winters. Onions, Carrots, and Cauliflowers are amongst the first to be attacked, but if they remain free until July it is very seldom they are much injured afterwards. For this reason many who are unable to grow some crops owing to the destructiveness of the grubs in spring may safely sow or plant in July. Globe Artichokes are wonderfully fine this spring, and we account for this through their not being frosted down last winter. Many say they did not like this vegetable, and if they have only had experience of small heads we are not surprised at their impression; but large succulent heads, especially of the Green variety, are really delicious.

Planting Broccoli.—These should all be put in their bearing quarters as soon as possible. We plant large quantities between late Potatoes, and we find them succeed well in such positions. The plants should not at any time be grown closer together than 18 inches each way, and some of the stronger-growing varieties should stand 2 feet apart; but we do not approve of growing them 3 feet or more asunder in order to get extra large heads, as medium ones are the most serviceable. Where the plants are growing close together in the seed rows they must be eased at the root with a fork, then draw them up, wet all the roots in a paint-like

mixture of soil, soot, lime and water, and dibble them into their places. This operation will keep the plants fresh, and few insects will attack the roots with such a compound about them. Kale, Savoys, Brussels Sprouts, and Winter Greens should be treated in the same way, and the sooner the better.

Turnips.—Sow a large quarter of Veitch's Red Globe for use in September and October. Thin out young crops, use as many roots as possible of those which are ready, as they will not remain long tender, cool, and sweet. Pull up all those going to flower, and fill up the ground with other crops.

Late Peas.—The sowing of these should now be completed. Suttons' Latest of All is what its name implies, and is also one of the best. Moderately rich cool soil is the best to sow in now. Clear off early crops as soon as the pods have been gathered, use the stakes for latter ones, and fill the ground with other crops. There should not be a square yard of unoccupied ground in any garden at this time. Peas being grown for exhibition should have the points taken off each stem just above the second or third pods, and give abundance of strong liquid manure at the roots. The pods should be well filled, no empty corner at the end, and at the time of showing they should be well developed, yet tender and green.

Small Salads.—These must be sown frequently now, especially Mustard and Cress, and Lettuce also require attention in this way. A pinch of Endive seed should be sown to produce a few heads in the autumn, but it is too early to deal with the main crop.

Watering.—This is now receiving more attention from us, as the weather has become warm and dry, but we entirely disapprove of surface dribblings, but when water is required a thorough drenching is given, and no more is needed for a long time. Newly planted Celery often stands in need of water until established. Peas are greatly benefited by it, and so are Kidney Beans and Cauliflowers.

Mulching.—This is another good practice, and many vegetables are greatly benefited by it. Peas and Beans delight in having a layer of manure placed along each side of the row, and Cauliflower and others of the class thrive admirably when their stems are surrounded with manure. A mixture of lawn cuttings, horse droppings, and decayed refuse is most suitable for mulching vegetables.

Vegetable Marrows.—These are now showing plenty of flowers, but at first many of them fail to form fruit. A good remedy for this is to pinch the point out of each shoot just before the blooms open, and when it is seen that there are many fruits on the stem. Fertilising the flowers also helps to make them swell, and dryness at the roots will spoil all.

Hoeing.—No one will make a mistake in doing this now. "When there is nothing else to do, always hoe" is our order at this season, and there are many advantages connected with the practice, as an open clean surface is beneficial to all crops.

Raking.—Many who pay more attention to dressing and keeping than sound cultivation devote much time to raking between their kitchen garden crops at this season, but more harm than good results, as, except on the score of appearance, raking and making the surface very fine is superfluous work.

FRUIT FORCING.

VINES.—**Late Houses.**—The final tying-out and thinning of late Grapes will require close attention, otherwise surplus bunches and rapidly swelling berries will rob the fruit which it is intended to leave for ripening. The best time for thinning is the early morning and in the cool of the evening; but at those times care must be taken that the hand does not come in contact with the berries, as this, though it may not show any immediate effect, very often plays an important part at the finish. Colouring depends to a great extent upon the removal of surplus bunches, and finish is the result of careful thinning of the berries. It is impracticable to lay down any rule for thinning, as the Vines even of the same variety differ, some finishing much finer berries than others. The aim should be a selection of the perfectly fertilised berries, leaving them sufficiently numerous to form a compact cluster that will hold itself in form when laid on the dish.

Watering.—When Vines are in active growth the roots must have moisture; if it is not given at the surface the roots will strike down in quest of it. Hence it is better to keep them within the influence of air and sun by liberal surface supplies. Vines swelling off their crops should have a good soaking with tepid liquid manure or guano water at the rate of 1 lb. to 20 gallons of water, applying it at a temperature of 90°. These remarks apply more particularly to inside borders, but outside borders that are well drained should have similar attention in dry weather. In wet weather outside borders will not of course need water, but they ought to be mulched so as to keep the surface moist, attract and keep the roots there.

Temperature.—Fire heat will only be necessary to keep up a minimum of 65° for Hamburgs and 70° for Muscats, which should be accompanied with a circulation of air to keep the moisture from condensing on the leaves and berries. Increase the ventilation to 70° for Black Hamburgs and 75° for Muscats, allowing the temperature to advance with the increased solar heat, keeping it at 85° to 90° for Muscats, and 80° to 85° for Black Hamburgs through the day with sun heat, and close early with plenty of moisture in the house, sprinkling the borders and paths with clear liquid manure.

Young Vines for Next Year's Early Fruiting.—When the Vines, whether in pots or planting out in borders, give indication of ripening, the ventilation should be increased with a gradual reduction of moisture, but there must not be any attempt to ripen them suddenly by withholding

water, though the supply will need to be lessened, and the foliage must be preserved clean and healthy as long as possible by the free use of the syringe.

Cucumbers.—The most important point now is daily attention to the management, and as the weather is suitable without resort to fire heat, the plants are growing rapidly, and will require thinning two or three times a week to prevent overcrowding. Stop one or two joints beyond the fruit, and remove all surplus and ill-shaped fruit, as overcropping is injurious to the continued fruitfulness of the plants. Use the syringe early in the morning and at the time of closing in the afternoon, after which the temperature may rise to 90°, and after the house has been closed about three hours admit a little air for the night. Commence ventilating at 75°, increasing it with the sun heat, keeping through the day at 80° to 85° or 90°, and close at 80°. Syringing will be sufficient to keep red spider in check, but if it should obtain a hold syringe with clear sulphur water late in the evening, well wetting the stems, foliage, and walls, and shade early the following day, and if the spider be not subdued repeat the syringing. Supply tepid liquid manure at every alternate watering, and afford a top-dressing of lumpy loam and a fourth of well-decayed manure. Shade only to prevent flagging.

Plants in Pots and Frames.—These will need to be examined twice a week for stopping, thinning, and regulation of the growths, never suffering them to become overcrowded. Employ glasses for keeping the fruit straight and free of the blanched hue, which is produced by close contact with the soil. Admit air early in the morning—a little at 75°, and increase it with the solar heat, closing at 85°, damping overhead at the same time, and if the temperature rise to 90° it will be an advantage. Keep the temperature through the day at 80° to 85° from sun heat. Water will be needed at the roots about twice a week, and if liquid manure be necessary apply it without wetting the foliage. Aphides are sometimes very troublesome, and the best mode of destroying them is by fumigation, but the plants must be prepared for it by allowing the foliage and bed to become dry and reduce the temperature. Fumigate lightly, and on two or three consecutive evenings, and be careful to have the smoke cool, so as to prevent scorching. Syringe early the following morning and shade before the sun affects the foliage. The same remedy is applicable to attacks of thrips.

PLANT HOUSES.

Allamandas.—These plants, as well as Clerodendrons and Bougainvilleas that are grown in pots and trained upon trellises, can be used for decoration in the conservatory or any other cool structure kept gay with flowering plants. The two former should not be removed until they are well in flower, while the latter if allowed to develop its beautiful bracts in a cool temperature are much lighter in colour than when expanded in stove heat. Previous to the removal of these plants they must be carefully prepared by gradually hardening them, for upon this the duration of the flowers depends. When these plants are used in cool structures the supply of water to the roots must be regulated with caution, for they will not need such liberal supplies as would be the case if kept in the stove.

Achimenes.—The earliest started plants are now in full beauty, and may be carefully hardened for decoration in the conservatory. In this structure they are much more beautiful than in the stove, for they do not become drawn so quickly. Their growth is slow and sturdy, consequently they flower with such freedom that they are highly effective amongst Pelargoniums, Calceolarias, and other flowering plants. The specimen pots and pans raised by inserting cuttings thickly together are decidedly better than those raised from the tubers, although a week or two longer in coming into flower. A very large stock can soon be raised by employing cuttings, for a few pans of tubers started early in the year will yield batches of cuttings in succession through the whole year. No plants are more easily grown and none more useful and beautiful for the various purposes of decoration. Numbers of these should be grown for conservatory decoration during the summer months instead of so many Zonal Pelargoniums.

Crotons.—Plants that have become too tall for decoration in 5 and 6-inch pots should be headed down and their tops rooted. These strike freely in close moist heat at this season. In order to maintain a supply of these plants in the best possible condition for decoration, a few should be propagated at intervals of a few weeks, for as soon as a plant becomes tall and unfit for the purpose the top should be rooted without delay. To have these plants well coloured for decoration they should be grown in full sunshine and close to the glass. Ventilate in preference to shading, closing the house or pit in which they are grown early in the afternoon. It is difficult to imagine any plants more unsightly than Crotons for decoration when badly coloured.

Dracenas.—These plants need almost constant attention in propagation when required in small pots for room and other decoration. Heads make the best plants, as they are furnished at the base with well-developed foliage, which is not the case with those raised from roots and the stem. It is almost impossible to maintain a supply of good heads for this purpose where many are used and injured in rooms. The only system by which this can be accomplished is to raise plants from the stem and roots and grow them on until they form good heads, which should be taken off and rooted. The tops of these plants root freely in a cool moist house if shaded from strong sun, in fact very much better than they will do in a propagating frame.

Nepenthes.—Cuttings that are inserted as advised some time ago are now rooted, and, if gradually hardened to the more airy condition of the house in which they are to be grown, may be placed in baskets 6 inches square or into larger pots. When grown suspended from the roof the

former are preferable, because the pots give almost constant labour in washing to keep them clean. These plants will grow well in sphagnum, peat, or loam, but when grown in baskets peat fibre is the best. Shade from strong sun, syringe frequently, and give abundance of water.

Gloxinias.—Seedlings raised from seed sown in the early spring and now established in small pots should be placed in 5-inch pots and grown close to the glass in an intermediate temperature where they can be kept shaded from strong sun. These plants will grow in a much cooler house than many suppose, and the flower stems will be sufficiently strong to support their blooms, which is not the case when forced in strong heat. If a little seed is sown at the present time, and the young plants grown and flowered in the size pots named above, they will be found most useful late in the season.

THE FLOWER GARDEN AND PLEASURE GROUND.

Surplus Bedding Plants.—In most gardens the bulk of the bedding-out has been completed ere this, and a few hints regarding the disposal of the surplus plants may be of service. Where there is a reserve garden used for storing evergreens and other plants from the flower garden, these are also available for the summer and autumn propagation of various hardy and tender bedding plants. Those not possessing this convenience should yet endeavour to devote a few good plots of ground in the kitchen garden or elsewhere to a similar purpose. The various sorts of Pelargoniums especially are seldom struck early enough in the autumn to become sufficiently strong to stand a dull winter. Neither the gardener nor the employer likes to see the beds interfered with during August, yet it is during this month the cuttings should be taken off. Those, then, who can plant a given number of each sort, as well as all those that are valuable and scarce, on a sunny well-manured piece of ground, should do so, and thus be enabled to cut them freely and as early as they choose. To be successful with Verbenas it is necessary to start with strong clean cuttings, and these can seldom be procured from those plants growing and flowering in the ordinary flower beds. Place out a few young plants on well-manured ground, mulch with short manure, and water occasionally with liquid manure, also pinch off all the bloom, and the result will be abundance of strong sappy growths from the main stem, and it is these which strike freely in August or early in September. The same treatment exactly meets the requirements of the Violas, Ageratums, and Lantanas. Lobelias will also yield cuttings in the same way. Many, however, depend upon old autumn-lifted plants to furnish the requisite number of cuttings, but neither Lobelias nor Heliotropes, Verbenas, Iresines, Coleuses, and Alternantheras can be transplanted and wintered with any certainty, especially if at all injured by early frosts.

Our plan with Lobelias is to place a number of young plants thinly in boxes of good soil, standing them in a cool open position, preventing flowering, and wintering them in a cold pit. In the spring every plant may be divided into a considerable number of already rooted pieces, and plants thus easily obtained are much preferable to seedlings. It is also advisable to keep a number of Alternantheras in well-drained boxes of light and fairly rich soil. During the summer they should be stood in a warm open position, kept carefully watered, and be housed before the cold autumn rains are experienced; or if they have to be wintered on the shelves of warm houses they may be potted off during August. A few of each sort of Iresines and Heliotropes may well be potted, using 5-inch pots and rich light soil. These will be serviceable decorative plants, and be sufficiently strong to furnish abundance of cuttings in the spring.

Surplus plants of Sempervivums, notably *S. tabulaeforme*, should have their centres cut or picked out, and this will induce the formation of a number of side shoots, which may eventually be taken off and grown into plants for next season's service. *Echeveria metallica* may be similarly treated, and any old stems from which the tops have been cut and rooted will also furnish a succession of cuttings. Old plants of a good strain of Golden Pyrethrum should be replanted for the purpose of seed-saving, as the strains supplied by some seedsmen cannot always be depended upon.

THE BEE-KEEPER.

PREPARING STOCKS FOR NEXT SEASON.

FAILURES in bee-keeping can often be traced to improper management in the preceding season, which by careful thought and attention might have been averted, thus saving the bee-keeper much trouble and disappointment. Arrangements and preparations for next year should at once be made. Whatever kind of hives are decided upon, let them be thoroughly clean, and, if old, disinfected; have moveable floors, and better if these are made of perforated zinc, having five holes to the inch closed on the under side with wood, so that a recess be formed between the two that the debris will not lodge on the upper floor but fall underneath. The usefulness of these floors, in addition to what I hinted in a previous article, is that when bees are troubled with parasites during warm weather, when they rid themselves of these pests they fall through perforations to the floor underneath (which is easily removed), and can therefore be destroyed in great

numbers. These zinc floors, too, are much more easily disinfected than wood. So well pleased am I with them in every respect that I will neither recommend nor use any others. One objection may be raised by those having round or octagon hives requiring for easy working square floors, but this objection is easily overcome. A belt or rim of strong zinc is made the size and shape of the hive at least 1 inch deep. The perforated zinc is now soldered to the upper edge and wood is fitted in beneath, the centre of it being made to slide out and in for ventilation and cleaning, which is easily done if the bearings are on the outer edges.

Another important matter in hives is to have the mouth or entrance extending at least 1 foot with a regulating slide. Many entrances are by far too small, but where perforated zinc is used these may be less. Whenever bees crowd out and fan much it is a sign that ventilation is required. When this is neglected the incoming of honey is lessened, while overheating with a chill immediately after is certain to cause foul brood.

The crowns of the hives should have all arrangements necessary for supering and insensible upward ventilation. Straw hives should have the centre hole covered with perforated zinc, and have slits for supering at the outer sides. Frame hives would be much improved if lateral slides were attached to every frame, but perhaps it will be difficult to persuade those used to the old style of frames, so I will address myself to new beginners, supplementing what I have already said on the subject. The bee-keeper must bear in mind that no hive is large enough unless it contains within its walls not less than about 1800 superficial inches of double-sided comb, and this comb should never be disturbed unless when actually necessary. All surplus honey should be obtained from supers.

The form of the hive in this variable and uncertain climate is of great importance. Look at a swarm suspended on a bough; then you get the idea that the circle, if not too wide, is the natural form, and the one in which the bees will thrive best and store most honey.

The next point to consider is the stocking of the hive. That should be done immediately, so that the hive be thoroughly filled with combs made from honey, for be it observed that combs made from sugar are more brittle than those made from honey. Care should be taken that there be not an excess of drone comb. The bees having young queens are not so liable to make drone comb as those having an aged queen. Then all hives should be filled this season, as when space is left to be filled next spring drone comb is almost sure to be built. Where comb foundation is used it encourages bees to build worker comb, but not always. Straw cylinders fitted with bars and frame hives are easily managed and drone comb controlled. It is different with common straw hives. Foundation cannot be used in these to advantage, but one advantage they possess over all others is, with their "ram-horn" combs the bees are provided with the best wintering hive in existence. A mere handful of bees in such hives, if kept dry, will not only survive the severest winter, but will often advance and pass those four times their strength located in the beautiful modern straight combs. Bee-keepers find such large straw hives cheap, and, cheaply covered, putting the swarms into Stewarton hives with combs which have been kept over from the previous year, perhaps the easiest and most profitable system of bee-keeping.

To fix the foundation in frames, the safest and easiest plan is to have a groove in a bar one-eighth of an inch deep; in this put the sheet. Lift with a teaspoon from a gluepot the melted wax, hot, but not boiling. Pour the wax first on one side, then on the other as the first side sets, holding the frame slightly inclined so that the wax runs freely from the higher end to the lower one. If the sheet is full-sized it will be necessary to "clasp" the sheet on each side by a piece of bent tin or zinc which is wide enough to pass over the bottom bar. Whenever the wax is set turn the frame on the end and place in position. Full-sized sheets should be about three-quarters or half an inch from the bottom rail, but should nearly touch the ends of the frames. This allows for the vertical stretching of the sheet, and insures the frame being fastened to the ends, so that the combs are rigid in the frames, and insuring safe manipulation and preventing collapse when in transit. To insure the comb being built to the bottom rail I allow a space of five-eighths between the bottom of the frames and the floor; this bottom space admits a fountain-feeder when necessary. When full sheets are used a few holes for passages should be made in the sheets by passing a hot wire through them where required. When bees are put into sheets of full size give them the scope of the hive until they have extended and secured a position; then, but not till then, they may be contracted if necessary. As in contracting a swarm into little space the combs are liable to collapse, at no time should bees be confined too

much; always give allowance so that their working is not interfered with.

As feeding is a necessary evil, and taking combs and honey from stock an unnecessary evil, avoid both as much as possible. If properly managed there will never be an excess of honey in stock or brood nest then. When a stock hive's stores are not interfered with, the pollen, so essential for breeding in spring, is not destroyed. With abundance of honey and pollen in store the bees are prepared to begin in the spring under very favourable circumstances, and will amply repay the bee-keeper with an abundant harvest for the little extra honey left in the hive in autumn. Of course no such hive is to be allowed to enter upon winter with other than a young queen of the current year. It is advisable to apportion a number of hives as non-swarmer. This is best effected, and, in fact, the only sure plan to prevent swarming, is to have roomy hives with a young prolific queen, attention being paid to under ventilation and to pile on supers as required. The proper time to do so is when the previous one has been well combed.

If the apiarian pays strict attention to the foregoing hints he will be satisfied with the results, while he will be saved from much trouble in feeding and anxiety for the safety of the bees, and will in the end have more honey than under any other system; foul brood and dysentery will be of rare occurrence, and the combs will be always fresh and sweet. The following will more fully illustrate the outline of management and give an idea what is required. It may not be out of place to mention here one case of profit from bees. A gentleman with whom I was acquainted made on an average for many years £30 sterling from six hives. Assuming a person is desirous of keeping a few hives, say a dozen, I would advise these to be composed of six large straw stocks stocked as advised. Six similar empty ones will be required to put the second swarms into to form stocks for next season. The six top swarms I would put into four Stewarton hives. Two of these would be stocked with single swarms, the other two with two swarms each; this makes up the six top swarms. These four hives will require say a dozen supers. For non-swarmer hives I would have two Stewarton hives complete, with at least six supers for each stock; the remaining four I would have frame hives, as these, or square Stewartons, are best for queen-rearing; but as there are so many ways of managing frame hives I will leave that to the inclination of the bee-keeper.

These eight hives in an ordinary season will have increased to eighteen, which may be reduced to the original number kept or sold. The six old straw hives at the end of three weeks from swarming should be turned, and the bees returned to empty hives; or, perhaps, better to join these to the second swarm, which must not be interfered with, unless the protracted season may have allowed them to fill supers. The four Stewartons must now be deprived of all heavy top boxes, the under ones stocked with pollen carefully preserved till next season, and the bees of these added to the two non-swarmer ones, the surplus honey of which has also been removed. It will now be clear that the great advantage gained and to be gained by having strong hives must be giving the greatest amount of honey and least trouble with the fewest stocks. It is impossible for anyone to give accurate instructions beforehand, so much depends on the situation and the weather; but it is a fact that the greatest number of bees always gather the greatest amount of honey both in poor as well as in rich districts.—LANARKSHIRE BEE-KEEPER.

ARTIFICIAL SWARMS.

CAN I without risk of loss take artificial swarms from two stocks in separate boxes but only 1 foot asunder? There is plenty of space on the outer sides. If so, how?—T. M.

[Artificial swarms can be taken in the ordinary way. Be sure the queen is with the driven bees, then remove old stocks as far away as possible. Also be sure that sufficient bees are left in the old stock, so that the brood does not suffer. Place the awarms on the old stock's site, and imitate its appearance as much as possible. If boxes of the same size were used the floorboards under the old stocks might be placed under the new swarm; but as there is danger in perpetuating foul brood by this plan, if it has been present in the old stock, it will be safer to try them without, as generally speaking, if old stock is far removed there is no difficulty at this season.]

LATERAL SLIDES.

MANY thanks for your reply to my query about supering and for the suggestions of "A Lanarkshire Bee-keeper." With the appliances that he mentions all difficulty would cease, and if I ever buy any fresh bar-frame hives I shall not forget what he says. My hives have neither slides nor adapting boards, and of course the quilts are at once propolised. "A Lanarkshire Bee-keeper" speaks of a lateral slide for every frame. I have

never seen such lateral slides, and should be very glad to know if they can be adapted to ordinary bar-frame hives, either empty or inhabited ones. I have never used carbolic acid when doing anything among bees. I hope soon to take some honey, and as the sections are all open at the top I shall try the effect of the acid if the disposition of the bees seems to render it necessary.—PHILOKEPOS.

[Lateral slides can be fitted to inhabited hives. Any handy person can soon mount empty ones. Procure some clean one-eighth-of-an-inch wood cut into strips the length of top bar and $1\frac{1}{8}$ inch broad. Now, if the frames have not broad shoulders make them so by nailing on pieces of proper size, so that the frame when finished will measure $1\frac{1}{2}$ inch broad. Then bend pieces of tin or sheet brass between a backflap hinge, so that the frame will measure $1\frac{1}{2}$ inch broad when bent and an eighth more than the thickness of the frame. This one-eighth allows the thin slide to run beneath, and if one side is checked one-quarter that allows them to be either close or any width up to a quarter of an inch. Any propolis bees use on these slides does not hinder in the slightest any manipulation. If the foregoing does not enable "Philo-pekos" to proceed, a sample frame can be sent him by applying to Messrs. George Neighbour & Sons, 149, Regent Street, London. They will supply him with these or a pattern.]

TRADE CATALOGUES RECEIVED.

J. Sylvester, Idle, near Bradford.—*List of Dahlias and Bedding Plants.*
Francis & Arthur Dickson, Upton Nurseries, Chester.—*Catalogue of Stove, Greenhouse, and Bedding Plants.*
Dammann & Co., Portici, near Naples.—*List of Bulbs and Roots.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Cucumbers (H. G. B.).—We are obliged to you for the examples, but they are insufficient for the purpose.

Long-podded Bean (R. C. F.).—The name of the Bean of which you have sent pods is *Dolichos sesquipedalis*, or a variety of it. The pods are eatable in a young state, and the plants would probably succeed in rich soil and a warm position out of doors in summer, but better under glass. It will be referred to again.

The Germander Plant (R. H. R.).—We did not receive your first letter, or it would have been attended to. The common Germander is *Teucrium Chamædrys*, which is esteemed chiefly as a mild aperient and corroborant in uterine, rheumatic, gouty, and serofulous affections, and intermittent fevers. It formed an ingredient in the once celebrated gout medicine called Portland powder. *Veronica Chamædrys* is also known as the Germander Speedwell, and has been used as a substitute for tea.

Vine Leaves Deficient in Chlorophyll (J. W. B.).—The leaves you sent, though large, are thin, and the cells in the spaces between the veins are deficient in green colouring matter (chlorophyll), which causes the light appearance. This is probably due to overcropping and weakness, as the cell growth has exceeded the supply of nitrogenous matters necessary to the formation of the chlorophyll. A similar result is seen in the case of many etiolated or blanched plants that have been grown rapidly either in great heat or a dark position, the strength of the plants being exhausted in the cell-increase, and contain little besides water. Possibly also there is not sufficient potash in the border, as this often has a similar effect.

White Maggots in Garden (Anxious).—White maggots can usually be destroyed by watering the plants attacked with clear lime water, but one application will not suffice. It is safe, and you cannot make it too strong provided it is perfectly clear. Brown leathery-looking maggots are more difficult to extirpate, and in reference to these see our reply to another correspondent. If the present angle iron supports are insufficient for your stage we can only suggest that you obtain stronger or place them closer together, with upright supports of wood or masonry for rendering the stage firm.

Seaside Shrubs (W. D.).—No evergreens are grown so extensively at Brighton and other fashionable resorts on the south coast as *Euonymus* are. The luxuriance of these shrubs at Brighton is surprising to persons who have only seen examples in inland gardens. There are a number of varieties,

but we do not know of one exactly answering to the description of a "Portugal Laurel with light green foliage;" it may, however, be *Euonymus latifolius*. If any of our south-coast readers can give any further information on the point they may feel to be needed we shall be glad to hear from them.

Grubs in Garden (*M. M., Co. Down*).—There appears to be a plague of maggots this year, yours being the third letter of inquiry on the subject this week. We can only refer you to our replies to two other correspondents and recommend you to try the remedies suggested. We believe petroleum as burned in lamps will be effective, if you can ascertain by experiment the quantity to use with safety. It mixes better in water in which a little soap and soda have been dissolved than in pure water. We shall be glad if experiments can be made both with petroleum, hellebore tea, and lime water in eradicating grubs, and if mixtures can be prepared that will accomplish this and yet not injure plants the particulars will be very acceptable.

Seedling Fuchsias (*J. B., Ruabon*).—The flowers were unfortunately much crushed in transit, so much so that the sepals of all the expanded flowers were bent quite back to the tubes, so that we are unable to distinguish clearly which variety you allude to as the "reflexed" one. The question, however, is not material. The flower with the short tube has unusually rich sepals, bright coral red, and the corolla, much crushed, seems to possess substance. This we think the most meritorious, and likely to be effective for decorative purposes. The other with long tubes is also attractive, and if the plant is a strong grower would be admirably adapted for training to a roof. Although both the varieties are worthy of preservation, we doubt if they would be regarded of any commercial value by a florist, as there are so many varieties with better formed flowers in cultivation; still, the apparent freedom of growth and floriferousness must render them useful for greenhouse and conservatory decoration.

Grubs in Mushroom Bed (*C. F. T.*).—We are not acquainted with the particular grub which you describe, nor is Mr. Barter, whom we have consulted; but for various kinds of insects he finds either flowers of sulphur or lime sparingly shaken over the surface of the beds a good preventive, or even water slightly salted—say, by mixing 1 to 2 ozs. of salt in a gallon. The only matter in which we are able to adjudge you "wrong" is in not detecting the enemy sooner, and preventing the attack becoming so serious. We are glad your outdoor beds are bearing so splendidly. Try the effect of the salt first, as this will not render the Mushrooms that may be on the bed distasteful.

Destroying Weeds on Walks (*J. C., Cheshire*).—A short time ago several methods were described in the Journal of destroying weeds on walks. Salt is only objectionable by making some walks too moist. In the case of dry walks and positions this objection vanishes, and applied in dry weather salt is effective. Arsenical solutions will kill weeds. Boil 1 lb. of powdered arsenic and 2 lbs. of crushed soda, then dilute with seven gallons of water. Add one part of common vitriol to thirty parts of water, mix and apply. Mix an ounce of crude carbolic acid to each gallon of water prepared, and with this water the gravel. Petroleum will kill weeds; the quantity to use you can easily ascertain by experiment. Whatever is used, Box or Grass edgings must be protected.

Melons Cankered and Leaves Scorched (*G. S.*).—When the scorching of the foliage accompanies the cankering of the stems we always have a suspicion that the soil in which the plants are growing is too wet on the surface and too dry below. Ascertain if this is not so in your case, and if the soil excavated from the bottom of the bed is in the slightest degree dry apply water repeatedly until it is moist. In watering Melons, though we give copious supplies, we never apply it within an inch of the stems, and have no canker. A mixture of lime and powdered charcoal is a good and safe application, but two handfuls at a time is a needlessly large application. A correspondent, Mr. Waiting, has found powdered alum efficacious, but we have not had an opportunity of testing the merits of this. You might try it, and let us know if it answers better than the lime and charcoal. The Fern is *Davallia bullata*.

Soil for Vine Border (*Inquirer*).—Of the two samples sent No. 2 is in our opinion by far the best both for Vines, Cucumbers, Melons, and plants generally that require good loam. No. 1 contains practically no humus, and on the decay of the fibre would run together like a lot of silt. No. 2 would also we think run too closely together in a border. Vines would grow well in it for a few years, but afterwards less satisfactorily if no measures were adopted to encourage surface roots, and nothing added to maintain the porosity of the soil. We should add wood ashes, bones, and lime rubbish with it for a permanent border, and decayed manure or leaf soil for plants in pots and Cucumbers. It will form the basis of a very good border and for general potting purposes.

Grubs in Soil (*G. L.*).—If the grubs are the maggots of the daddy long-legs you will find them extremely difficult to destroy. As grubs attack Lettuce and Cabbage plants recently planted it is advisable to scrape the soil from the plants and place a mixture of soot and lime round them, which will act as a useful barrier against the attacks of the depredators. Watering with a solution of petroleum at the strength of half a wineglassful of the oil to a gallon of water may also check the grub ravages, and act as a manure. A solution of hellebore may also be of service, beating 2 ozs. of hellebore powder into a paste with boiling water, then adding a gallon of cold water for use. You might try these suggested remedies and favour us with the results. Gas lime dug into the ground in the autumn would be beneficial.

Grubs in Eucharis Bulbs (*J. S.*).—We are quite unable to keep in mind the particulars of former letters pertaining to subjects which have been replied to; and when further information is needed the circumstances pertaining to the first inquiry should be recapitulated. If mites are in Eucharis bulbs it will be difficult if not impossible to destroy them without injuring the bulbs. Immersing in clear lime water is one of the safest and best of remedies; then place in small well-drained pots, using turfy loam and an admixture of crushed charcoal, surrounding the bulbs with a little powdered charcoal, and if convenient plunge the pots in bed where they can have bottom heat of 80° to 85°, giving water sparingly until roots are working freely and fresh leaves are produced, when more copious supplies will be necessary.

Exhibiting Roses (*A. A.*).—The blooms should be exhibited in boxes, the stems of the blooms being placed in tubes filled with water, the tubes being embedded in moss, the smoothest and freshest of which should form an emerald surface to display the blooms to the greatest advantage. Each bloom should be cut with as much foliage attached to the stem as possible, but no leaves must be added. If the blooms are cut on the morning of the show they should be secured early and before the dew has evaporated from their petals. The moss in the box must be moist, and the blooms should be arranged so as to stand a few inches above it. Many new beginners spoil their boxes by pressing the blooms close down on the moss. The boxes should have lids, which, especially on sunny mornings, must be kept over the blooms until the last possible moment before the judges enter the show. The subject will be referred to again, and further information given that may be of service to you.

Thrips on Vines (*C. J.*).—Having been a grower of Grapes for forty years you must consider yourself fortunate in not having previously become acquainted with the insects now attacking the foliage—thrips. The attack is, moreover, we are sorry to observe, rather a serious one, and if the insects are not checked they will seriously injure the Vines. Possibly you may have had *Azaleas* in the house, and with these introduced the pest; however, be this as it may, the insect must be extirpated. Fumigations with tobacco or tobacco paper will destroy thrips, the house being moderately filled with smoke on two or three consecutive mild evenings when the foliage is dry, repeating the process in ten days, as other insects will have then hatched from the eggs, that are numerous. Syringing with an insecticide will not be effectual, inasmuch as so many of the insects are on the upper surfaces of the leaves. If you have not many Vines we should have the leaves sponged with either nicotine soap, Gishurst compound, or softsoap and tobacco water, whichever may be at hand. Two ounces of softsoap dissolved in a gallon of water, and from half a pint to a pint of tobacco water added, according to strength, will answer if you cannot readily procure the prepared insecticides. A careful handy person may dress hundreds of leaves during two or three hours before breakfast, and kill thousands of insects. Tobacco smoke in moderate volume will not injure Grapes after they are stoned and up to the colouring period. Whichever method you adopt for eradicating the thrips, we advise you to act promptly.

Grapes Scalded (*A Lady Gardener*).—The injury is chiefly caused by extreme evaporation from the berries, and is the most prevalent when vineries are kept closed too long in the morning, and the sashes then thrown open so widely as to reduce the temperature of the house. Very early and gradually increasing ventilation in advance of the increasing temperature of the vinery is the best preventive, and there should also be sufficient foliage on the Vines to shade the fruit from the direct rays of the sun; failing this slight shade such as sprinkling whitewash on the glass is occasionally advisable. Early ventilation means opening the top lights slightly before the sun has been shining on the house half an hour. This often occurs by or before six o'clock in the morning, while many vineries are not opened until seven or eight o'clock, especially on Sundays. This delay is dangerous, and has often proved disastrous. The berries sent indicate that the Vines are healthy. Violent syringings will so far help to keep in check red spider that it will not do serious injury. Sulphur will check it, and may be mixed with water and applied with a syringe after a thorough washing with pure water. The leaf you sent arrived in a very shrivelled state; it appeared to be as much injured by scorching as by insects. If you have only a few Vines and insects are on the upper surface of the foliage you might have the leaves sponged with a solution of softsoap and tobacco water.

Market Measures (*G. P.*).—In Covent Garden a half sieve contains three and a half imperial gallons. It averages 12½ inches in diameter and 6 inches in depth. A sieve contains seven imperial gallons. Diameter 15 inches, depth 8 inches. A sieve of Peas is equal to one bushel; a sieve of Currants twenty quarts. A bushel sieve ten and a half imperial gallons. Diameter at top 17½ inches, at bottom 17 inches; depth 11½ inches. A bushel basket ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-named cleansed weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. A pottle is a long tapering basket that holds rather over a pint and a half. A pottle of Strawberries should hold half a gallon, but never holds more than one quart. A pottle of Mushrooms should weigh 1 lb. A hand applies to a bunch of Radishes, which contains from twelve to thirty or more according to the season. A bundle varies according to the supply. Seakale 12 to 18 heads; Rhubarb 20 to 30 stems, according to size; and of Asparagus from 100 to 125 heads. There is no book or paper published that gives the information you require. The published market prices are those paid by the buyers to the sellers of the produce, and are average prices for average goods. Articles of superior quality occasionally realise more than is indicated, while inferior produce fails to obtain the prices as quoted in the market returns.

Plum Leaves Silvery (*N. L. C.*).—We have many times, and in different places, observed the foliage of Plum trees assume a silvery appearance, and the branches afterwards die. We have also noticed that the occurrence has been most frequent when bright and dry days have followed a term of wet and dull weather. We have further found that the trees which have suffered the most were those with apparently fine healthy foliage, and that the leaves after the attack were harsh and dry like smooth paper. As we could not find any trace of insects and mildew to account for the condition of the leaves we attributed the cause of injury to sudden and extreme transpiration—a drying-up of the sap, and the consequent separation of the cuticle from the substance of the leaf, and the cuticle being transparent, must necessarily when raised impart to the leaf a silvery appearance. This is in substance what we have more than once stated; but with the object of gaining further information we submitted some leaves to Mr. Worthington G. Smith, who is an adept in detecting under the microscope, and delineating things hidden from ordinary observers. His reply was in accordance with our own views on the subject. He found the cuticle raised from the leaves and much torn, only adhering to the veins. He attributes this to the substance of the leaf shrinking or drying up, which seems to show that at one period of growth there was a too rapid formation of leaves, and then the growth ceased, and the too much distended material shrunk back and tore itself away from the cuticle. For this serious change to which Plums, and occasionally Peaches and

Laurels, are liable, we regret to say we know of no general remedy. We can only suggest in your case that if your tree makes gross growths to lift it in the autumn and place the roots in fresh loam with an admixture of calcareous matter, making the soil firm, and thus incite the emission of a number of surface fibres, these conducing to sturdier growths and smaller and stouter-textured leaves.

Names of Plants (Thorn).—3, *Viburnum Opulus*; 4, *Listera ovata*; 5, *Cytisus albus*; 6, *Geranium pratense*; 7, *Veronica Beccabunga*. The other specimens were too imperfect to be recognised. (*G. T., Oporto*).—A variety of *Oncidium sarcodes*. The Moss is *Mnium undulatum*, sometimes called the Palm Tree Moss. (*J. J., Lancashire*).—The Cattleyas are both varieties of *C. Mendeli*. The Brassia is *B. verrucosa*, and the Dendrobium is *D. crystallinum*. (*G. W. S.*).—We do not undertake, as we have many times stated, to name varieties of florists' flowers. (*Subscriber*).—1, *Picea pectinata*; 2, *Fagus sylvatica asplenifolia*; 3, *Viburnum Opulus*; 4, *Rhododendrum punctatum*; 5, *Pyrus aria*; 6, *A Sedum*, specimen insufficient.

COVENT GARDEN MARKET.—JUNE 18TH.

A FEW outdoor Strawberries to hand this week, prices being considerably affected. Best Peaches and Pines in demand. Trade as last week.

ARABLE AND PASTURE FARMING.

(Continued from page 478.)

WE must now refer to lands of less value, although not less important to the owners and occupiers—we mean pastures adapted only for dairy purposes, and more or less mixed in occupation with arable lands of many shades and varieties of natural fertility, except on the chalk hills. These are so extensive and form so large a portion of the landed property in the kingdom, that under the present depression in agricultural pursuits they involve, not only interests of unusual magnitude in a commercial point of view, but matters of very serious consequence to agriculture as well as many trades and callings, especially in the inland districts and provincial towns; in fact the welfare of the owners and occupiers of a great part of the land is intimately connected with the general interests of the kingdom. It must also be stated how these properties of mixed soils and situations can be best managed for the interests, not only of the owners and occupiers, but for the class interests of the kingdom also. For by the present mode of conducting many farms, whether occupied by a tenant or in the hands of a home farmer, they are often managed upon a system which is totally inadequate for contending with the difficulties peculiar to times of depression, arising either from a succession of adverse seasons, the low price of corn, or from the continuation of practices both in stocking and cropping ill adapted to the altered circumstances of agriculture, all this being illustrated by facts which are patent to all observers, and which have had serious consequences in connection with all persons connected with the ordinary farms both of arable and pasture land throughout the kingdom. To prove this we need only call attention to the ever-increasing area of untenanted farms, for we notice vale lands in some countries hitherto let (at least up to 1878) at high rents in consequence of the tenants' competition amongst themselves for possession of these farms. The aspect of whole districts is completely changed, so that thousands of acres are untenanted and left in the hands of the owners and the

home farmers in the most foul and reduced condition; and this is the serious condition with which hundreds of home farmers as well as occupying tenants have to contend at the present time. Let us ask what the world and the writers credited with representing public opinion say upon the subject. The cry is general that less corn should be sown and more stock must be kept, and these observations are made often without any reference to the soil or any kind of stock or system of cropping. The only remedy offered quite irrespective of soils or breeds of cattle is that more land should be laid into pasture, that more cattle should be raised including sheep, and also that less corn should be sown. We do not propose to listen to what is said upon such a subject, but in the light of our own experience will endeavour to formulate a mode of treatment by cropping and stocking, which is calculated to meet a set of new circumstances by which a large portion of the farmers of our country are surrounded.

As an illustration of a new departure compared with the usual and former modes of management the case of a farm of 200 acres may be taken, fifty acres being in pasture adapted for dairy farming. The late or former mode of cropping and stocking has been the four-course or Norfolk rotation for the arable, and the stock consisting of sheep to consume the produce of the root-lain upon the land, except a portion of the Mangold crop for feeding dairy cows and young cattle, including perhaps some bullocks fattened in stalls or boxes. The points of disadvantage attending this system of management are as follows: The root-lain being one-fourth of the arable, the Lent corn one-fourth, Clovers, &c., also one-fourth, and the remaining fourth being cropped with Wheat. The fattening bullocks in the boxes always receive roots, and when receiving hay and cake or corn in addition as usually given they do not yield any profit on the transaction. The sheep stock whilst feeding off roots on the land where they were grown do not pay for the roots, much less for the hay, cake, or corn frequently added; and after the working horses have been provided for, the residue of hay, roots, and grazing will not furnish sufficient food for many dairy cows and young stock, although they are really when well bred and well managed, as a butter-making, calf-suckling for veal, or a milk-selling herd the most profitable stock on the farm, commercially speaking. The only items for sale grown or produced on the farm under this system (the hay being all consumed, as also the roots) will be the Wheat crop and a portion of the Lent corn, the remainder being consumed by the horses and swine according to circumstances. Under this system there is only the manure which is valuable arising from the horses, the swine, the dairy cows, and young stock; and lastly the manure left by the sheep on the land where fed. But against this item we must bring forward a formidable indictment. These animals, even when liberally fed with hay and cake on the mixed or strong soils, tread the land to a great disadvantage during at least half the winter period whilst fattening; therefore one-half of the land is deteriorated and requires extra labour before sowing the Lent corn. On the other half one-quarter part is sown with Lent corn too late in order to accommodate the sheep; the remaining quarter part whereon was grown roots for use and consumption at the homestead by cattle, horses, and swine, which land will require to be manured from the farmyard before seeding with Lent corn. In adverse seasons, however, the sheep cannot always be sold when the root crops are finished, in which case they either feed on the pasture land to its injury or on the Clovers and Grasses on the arable, and thus reduce the hay produce for the next winter. How are the farmers to find under this the customary mode of cropping and stocking sufficient commercial profits to meet their engagements and all their expenditure? It cannot be done under the best of management, simply because the sheep and bullocks do not pay; and the short acreage of low-priced corn are totally inadequate to meet the comparatively fixed charges of rent, tithes, rates, and taxes, together with incidental charges for labour, tradesmen, seed and manure bills. Here leaving out various accidental contingencies is the cause most glaringly evident, which has produced those extensive failures to which we have previously alluded.

In order to avoid the difficulties which the foregoing mode of management imposes upon the farmers, a new system must be adopted, and for illustration we will take a farm of the same size as that already mentioned, including 50 acres of pasture adapted for feeding dairy cows and young cattle, the object being to produce butter, or veal, or milk for sale, but entirely dispensing with sheep. The rotation of cropping should be as follows, and commonly called a three-course:—First course, Wheat, 50 acres to be prepared for, as stated hereafter; second course, Lent corn, 50 acres of Barley, Oats, or dreg, according to the soil and situation, to be prepared for as follows: 20 acres, part of to be seeded with Greystone Turnip seed immediately after the Wheat is cleared off; a portion to be ploughed and sown between the lines of sheaves every day as fast as ploughed. The young Turnips to be ploughed-in as manure for the Barley to be sown in the following month of March, to be seeded with Red Clover and Trefoil in admixture with Cock's-foot and

Fox-tail grass seeds ; 10 acres part of to be ploughed and sown with Greystone Turnip seed, the crop to be ploughed-in as a preparation for White Canadian Oats ; 20 acres part of to be ploughed directly after harvest, and sown with Giant Rye and ploughed-in during the month of March as a preparation for drege corn. The preparation for the Wheat crop will be as follows :—20 acres out of Clover and grass lea, the second crop to be ploughed-in if the yard manure is insufficient ; 10 acres after White Canadian Oats to be Giant Rye, part cut up for horses and cows and part ploughed-in, but together ploughed and sown with Mangold ; 20 acres after drege, half to be sown with early Peas on the lightest land, followed by Mustards, and half seeded with winter or spring Beans mixed with Winter Vetches or late Partridge Peas. Under this rotation we grow 50 acres of Wheat, 50 acres of Lent corn, and 20 acres of pulse crops. As the rent-paying crops are Wheat, Barley, Oats, also Beans and Peas, according to the soil, it is, therefore, quite clear that large crops, both in acreage and acreable produce, is the chief point worth the attention of the farmer, especially when we consider that rent, tithes, and rates are comparatively fixed charges, and will be met most easily in the future by an increased acreage of sale crops. It makes all the difference between profit or loss whether half the land under tillage only is cropped with sale crops or is extended to two-thirds, for the fixed charges are the same in either case. Again, it is worth inquiry what real profit is contributed by sheep. Although they are in some cases said to pay the rent, let it be fairly calculated what remains as a commercial profit after charging interest on the large capital employed, and the heavy charges for labour directly and indirectly connected with sheep-farming. It ought to be considered that large outlays in feeding stuffs are made where sheep are said to pay the rent, accompanied by a reduced acreage of the rent-paying crops, delays of seed time, extra tillage required, the losses of the flock, which cannot always be controlled, and, finally, the crops consumed, or, commercially speaking, sold to the sheep, even at a very low price, nothing is left but the manure on the land. After estimating this, in comparison with other systems of cropping, it will be found that we can obtain or purchase manure cheaper than the sheep can make it. In conclusion, it is by comparison only that just estimates of anything can be made. Let it be made between sheep-farming and ploughing-in green or root crops as manure for the production of sale crops. For information upon systems of farming adapted for other soils we refer our readers to former numbers of this Journal under various headings.

WORK ON THE HOME FARM.

Horse Labour.—The mowing machine on the arable land and the scythe on the majority of meadow lands will now be in full work ; and the horses should not be worked on the machine more than four or five hours, and then take a change of animals for a similar time. In this way eight hours of horse labour will be found sufficient, except at carting and stacking of the hay, when the work may be considered in reference to circumstances only up to sunset. There was a plan formerly adopted which had our entire approval when the weather proved favourable for both hay-carting, preparing and drilling of Swede, and early Turnip seeds—that was to work in connection with cultivating and drilling for root crops up to about an hour before mid-day, and carting and stacking hay afterwards ; in fact the hay is always better in condition for stacking in the after part of the day than in the forenoon, especially where the weather is settled fine ; even then, however, we frequently get heavy fogs or mists in the mornings which often retard and delay the condition of the hay up to mid-day. In stormy weather setting in when the grasses and Clovers are in bloom, ensilage is then the best prospect for obtaining the best kind of winter fodder for home consumption ; but even this system as far as it has proceeded is not quite satisfactory upon all points, irrespective of the cost and providing of pits or silos, although a great improvement upon ordinary hay-making in our fickle climate, especially in a season like that of last year, when in most districts very little hay was stacked in really good condition. There is, however, another view of the value both of field and meadow grass as compared with its winter use, for there is no mode whereby more advantage can be obtained from an acre of grass than when used in its green state, being cut for soiling cattle daily either for fattening cattle or feeding young store cattle—that is, in making both meat and manure ; for we hold that the value of grass for making meat is much greater, especially when used in summer than when used as hay in the winter months, or whether grass has been secured either in the stack or in the silo, for we reckon also that the manure made from grass-feeding is of nearly double the value of that made from hay. It may be said that the hay will be required for feeding cattle in the winter ; but we ask why ? It has been proved by a common practice in Hampshire and other districts that when cattle get a full allowance of cut roots in the boxes, mixed with 4 lbs. of cake and 1 lb. of Bean or Maize meal daily, that good sound Oat straw is far better than the best hay for the bullocks fattening as regards not only their health and regular feeding, but also by the benefit shown on a debtor and creditor account. The hay-feeding adds at least 2s. 6d. per week to the cost of feeding, and frequently proves a clogging and indigestible addition to a well-arranged and adjusted system of feeding, in which case the cattle often refuse their food for a day or two, and thereby lose

flesh instead of gaining it, for Nature never stands still, but is either improving or receding more or less. The feeding of dairy cows at the stalls is a matter requiring a separate and further consideration, for no doubt the land will yield a heavier acreable produce when cut for soiling than when grazing, and the food can be the better adjusted as to a sufficiency for the production of a full record of milk than by the grazing system. This is frequently affected by the state of the weather not only as to state of the grass in extremes of wet or drought, but also as to the generally well-regulated condition of the cows as to grass-feeding at the troughs, but at the same time that of any artificial or supplementary food necessary for them to receive at the rack or manger.

Hand Labour.—Horses will now be fully employed hoeing the Mangolds and other early roots, such as Swedes, Cabbages, &c., and especially where the land is clean and the men can be depended upon to make fairly good work in setting out the plants ; yet it is hardly ever done so correctly in singling the plants as it ought to be. We therefore advise that women or young people should follow the hoers and single out the plants by hand-pulling, taking care to leave the strongest of them ; at the same time the hoers should be given to understand that they also should be the strongest plants within their reach, although they may happen to be a few inches wider apart than may otherwise be desirable. Hay-making, as well as cutting and collecting the coarsest grasses in the pastures, should now be carried on at intervals by making and carting hay, whether of Clover or Sainfoin, in fine weather, resorting to the work of filling the silos in damp or in weather unsuitable for hay-carting. It cannot, however, yet be said that many are prepared to secure grass in the silo for several reasons. The first is that they have not made any silo ; another reason that it is generally believed there is yet something to be learned as to the value of ensilage, and the best materials for making it, and the cost at which a silo may be constructed under varying circumstances of soil and situation.

Live Stock.—On the hill farms where large flocks of breeding sheep are maintained in the summer season the home farmer should look to the field and roadside ponds, because where they are judiciously constructed so that overflows of water during a thunder storm may flow into them they yield a valuable supply for the stock, especially in some instances where farms are often miles away from the rivulets, brooks, and springs of the vales. Dairy cows and young cattle should all have easy access to water by arrangement, or at the horse stalls, in which case it is a good plan to house them from ten o'clock in the morning to four in the afternoon in very hot and dry weather, taking care to make the stalls dark, for the flies follow the sunlight ; and at the same time let the animals have a good bait of green fodder in their racks at milking-time night and morning. This will enable them to hold on and lengthen the milking period, and improve the record of milk ; whereas if the animals are left in park or pasture lands in the shade of trees during the heat of the day, they are so distressed by flies that they will yield but little milk, and leave their droppings where no benefit will be derived. In those cases where calves are suckled for making veal instead of making butter or selling milk it may be made very beneficial, for it requires but little labour and but little risk, and for veal there is always a ready sale. There is at the same time no better plan of using cake or Maize meal than for feeding calves whilst suckling, as they can be held on until they are very choice in quality and of heavy weights. The plan is at first to make meal or cake into balls mixed with milk, and given as such they will soon learn to take it from the hand, and afterwards take it as pudding from the troughs. Large quantities of veal can be made in this way by the suckling of very few cows. In outlying situations there are no daily deliveries of milk or butter to the nearest town—an important point in dairy farming ; nor is there any difficulty of obtaining calves from the cheese-making districts of the midland counties or western border counties, as they can be now easily delivered by rail at short notice. We reckon the Devon calves make the best quality for moderate weights, the Herefords being next in quality of heavier weights, but the Shorthorn calves make coarser veal and more bony than the other breeds.

THE USE AND ABUSE OF THE WATERING POT.

NOW-A-DAYS, when so much is written by able cultivators on every conceivable subject connected with gardening, if a person waits until he can write on something new the probability is that he will never write at all. It is quite clear, however, that this is no valid excuse for silence, as abundant evidence is afforded on every hand that the old and essential routine practices are not thoroughly understood by all; nor is it likely they ever will be, since the young and inexperienced are always with us, and will be to the end of the chapter.

It may appear a somewhat strange, not to say bold, statement to make, that there are numbers of young gardeners in charge of good gardens at the present time who do not know how to dig. They do not even know where to begin nor how to finish a piece of land, while in such simple work as raking and mowing they betray their incapacity the moment they attempt to use the implements, and provoke the smiles of old practitioners. There is some excuse for this, as persons who are in many other matters competent have not had experience in outdoor duties. There is need, then, for plain teaching on plain subjects, and it is the more desirable to recognise this when it is remembered that the plainest of operations are the most important, and amongst the plainest of the plain is watering.

Although some excuse is conceded to a young gardener who may not be able to use the commonest of tools, the spade, rake, scythe, edging shears in a workmanlike manner, the same indulgence cannot be granted him for the mistakes he makes in watering, for he has been either using or abusing the watering pot day by day for years. During that time he has either endeavoured to make himself proficient by close and intelligent observation and attentive care, or he has gone on dabbling in a haphazard manner, and never quite sure whether he has been doing right or wrong; nor is he sure now.

There are numbers of such men engaged in gardens, to the great discomfort of the responsible gardener under whom they serve—that is, if he is a skilful cultivator and consequently an expert in the work in question; for no man can be either a competent grower of plants or fruit who is not first competent in the most important of all duties pertaining to that end—watering.

A young man who has made himself capable in the use of the watering pot, and can be trusted implicitly to exercise sound judgment and make few or no mistakes, is prized by his superior whose time is occupied in other duties, which he can discharge without any misgivings when he feels he is so well supported; but a slap-dash hit-and-miss kind of man, who gives too much water in winter and too little in summer, and who cannot or does not discriminate between the requirements of plants recently potted and those long established and crowding the pots with roots, is a hinderer rather than a helper—the cause of much anxiety, an impediment in the way of smooth working, an obstructor of success.

To be a good gardener a man must first train himself to the use, and not allow himself to indulge in the abuse of the watering pot. He must cultivate his perceptive faculties, and be able to judge accurately and quickly as to the real condition of a plant, and act accordingly. If water is needed it should be given promptly and sufficiently, if not needed it should be withheld until it is. There is no safe intermediate course. It is a great and far too common error to suppose that a plant may not be dry enough to be well watered, but sufficiently so to be half watered, hence a little is given to moisten the surface in the way of a compromise. This is a dangerous practice, and the more so since the person who commences it is exceedingly liable to continue until the habit is so firmly fixed that it is difficult to abandon and adopt a sounder and a better course. This slipshod manner of watering is the forerunner of half the failures in gardening, the origin of insects innumerable which instinctively attack enervated growths; it is the cause of nine-tenths of the failures by plants damping off, of half the cankering that occurs in the stems of Melons or Cucumbers, of multitudes of fruit not setting and swelling, of shoals of blossom buds falling—in fact, the abuse of the watering pot is the root of the majority of the evils and annoyances that occur in the career of the gardener.

Frequently, indeed much too frequently, there is no room for doubt as to whether a plant needs watering or not. Its flagging leaves and drooping flowers proclaim alike its urgent want and the neglect of some individual whose duty it was to have prevented such a collapse. The man who cannot foresee the requirements of plants, but waits the expression of their suffering—flaccidly hanging leaves—can never be a good cultivator, and plants that are subjected to that exhaustive treatment can never flourish, and the only thing thriving about them will be insects. And another thing, when plants are subjected to that negligent system of treatment, more time is occupied in keeping them in even a half-presentable state, and more water is used than if they are supplied in anticipation of their urgent need; for in the one case the water runs out of the soil nearly as fast as it is poured in, and the signal of distress, withering foliage, is seen again in an hour in hot weather. Plants thus managed or mismanaged may be watered four times a day and not be satisfied, while those properly treated by never being allowed to be actually dry will be well and sufficiently supported by two applications. There is no exaggeration here; the case is, in fact, understated, as all who are capable of judging correctly know full well. If it is an abuse of the watering pot to act on what may be termed the suffering principle, that involves both waste of water and waste of time, it would be interesting to know what it is. Nor does the abuse end in those two wastes, for there is a third—a direct and immediate waste of the virtues of the soil, which are positively washed away instead of being retained for the sustenance of the plants. The best loam may be purchased at a guinea or more a load, and all other ingredients for mixing with it may be of the best; the compost may be blended in the best possible manner, so as to contain exactly what may be needed for the sustenance of the plant, but the abuse of the watering pot will spoil all. A person competent in the use of the watering pot will produce far better results with inferior soil than will another who is incompetent yet having the best soil in the world at his disposal. This is no imaginative theory, but simple sober fact.

There are times, as all know who have had much experience in plant and fruit culture, when thought and discrimination are needed on the subject of watering. A plant may be neither exactly dry nor decidedly wet at the usual time when water is given. In such a case a moment's reflection is needed. If the plant has only been shifted for a few days it may be wise to pass it; if it is established and the pot crowded with roots it would be wise to water it. Plants in that intermediary state as to root-moisture may also be

safely passed occasionally when the weather is dull that it would be a mistake not to water if a hot day were pending. After long practice and close observation a man judges, as if intuitively; but this habit of quick and correct decision can only be attained by long and diligent watchfulness. It is lamentable to see the shortcomings of men in the important work in question, and to observe plants in their charge—on the one hand soddened by excessive watering before the roots have taken possession of the soil, and on the other hand established plants languishing by the lack of adequate support. A sharp rap of the pot with the knuckles and a moment's reflection on the condition of the plant and the prospective weather will usually guide the observant man aright.

Watering is something more than a mere routine operation requiring a certain amount of physical exercise. It is a mental process, and is as much a question of brainwork as is the writing of these notes. Let, then, the brain be exercised in the work under notice—indeed, in all work—and thereby strengthened; for as surely as the muscles of the blacksmith are developed by labour, so are the mental powers of man increased in force by healthy exercise. Without this there can be no skilled labour, and if a gardener is not a skilled worker he is nothing. He is simply playing a game of chance, and in nothing is he so likely to lose as in watering; as when he is deluded by the supposition that he is using the watering pot effectively, the probability is that he is abusing it all the time, and before he is forty years of age he is a disappointed man.—EXPERIENTIA DOCET.

AMONG THE FLOWERS.

OUT-OF-DOOR flowers are now yielding their richest harvest of bloom, and borders, beds, and clumps are gayer than at any other period of the year. True, the sentiment which has become attached to spring flowers is lacking. Drooping Snowdrop, blade and flower, has long ago disappeared, and we find no clumps of yellow Crocuses, with "golden-chaliced cups" shining in the mid-day sun, and haunted during glimpses of the "glorious king of day" by bees too easily tempted from their homes. No gaudy Tulips flaunt their buds of richest hues among sweet white Arabis or blue Forget-me-not, or Aubrietias of more sober tints. No Daffodils to tempt us maunder into rhyme, or retaining our sober reason to bury our noses in bunches of "Coddins and Cream," or Jonquils of richer scent, or the more harmoniously refined Poet's Narciss, and draw the subtle essence thence. Nor are our present-time flowers so stately or so glowing in colour as are the flowers of autumn. The day of the Dahlia is not yet, nor has the Hollyhock towered its stately spike above its compeers. We must wait for the queenly Gladiolus, the flaming Tritoma, and the large yellow Evening Primrose. Lovely Japanese Windflowers, and sweet-scented Phloxes, staring Asters, Sweet Peas, and Chrysanthemums—precursors of our early winter queen of flowers—are all to be waited for. But—and how shall I begin to select from so large a list?—we have Pinks, the very name carrying with it some of the sweetness of the flower. Pinks in hundreds, in row, in bed, in border, double white and double pink; and kinds like these, but with wondrous names, "Border Pinks" and forcing Pinks, Clove Pinks and florists' Pinks, and, only like in name, the splendid sorts of Mule Pinks. Pinks form a garden in themselves. What must a garden be without them, if such a one there be? Every garden, however, has its Roses, but it is not every garden which is possessed of Damask, York-and-Lancaster, Scotch, and Cramoisie Roses. These should all find a place in borders of perennial flowers, and, add to these Moss Roses and Cabbage Roses, Madame Hardy, Paul Ricaut, Coupe d'Hébé, Général Jacqueminot, Gloire de Dijon, John Hopper, and Géant des Batailles.

These are the kinds that men and women no longer young love to fondle and talk of to their grandchildren. Old-fashioned, no doubt, and obliterated most of them from present-day Rose lists, but Roses which bring forgotten memories to life, and, therefore, themselves instinct with living memories. Then here and there we find a clump of Heartsease—Pansies that were planted several years ago, and which have yielded their flowers at almost all seasons, but at none so so luxuriantly as at this. True, the flowers are not so large as the young thriving stock in a neighbouring bed, but on the whole their effect is much prettier, and we can cut and come again to these without any feeling of having behaved extravagantly. Some of the Violas are also found here; Alpha, for instance, with deep purple blooms, and in large masses, and Picturata, of a curious shade of lilac, but

telling in the extreme. We also find the dwarf white Rocket with Hyacinth-like spikes, and the taller-growing kind with looser spikes, and produced in greater freedom, and redolent with the never-to-be-forgotten scent of the common Rocket. Here are also the old dark double Wallflower and the little double yellow sort so seldom seen now; and more seldom seen still is the double Rock Cress, with its bunches of tiny button-like flowers.

Saxifragas in great variety are becoming dirty-looking, and the latest of the white perennial Candytufts (*Iberis corifolia*) will soon follow. The blue of the Gentianellas gives place to that of numerous kinds of dwarf Campanulas—pumila, Portenschlagiana, muralis, to garganica and its varieties, turbinata, carpatia, the Harebell, to taller kinds like Hendersonii, Van Houttei, the Peach-leaved varieties, and many others. Pyrethrums of themselves make quite a show, the taller-growing single kinds growing further back than those with double flowers. The same may be said of the Columbines, which have now begun their reign; cærulea, white and blue; vulgaris, none the less pretty for being a weed; californica, chrysantha, and nudicaule, some of them not yet in flower, but hastening fast forward. Then huge clumps of the many-fingered Lupin in white and shades of blue and purple, and variegated white and blue, make the almost flowerless background bright with flowers.

The Delphiniums also, with wondrous shades of blue and mauve, and spikes which yield to the Hollyhock alone, are now beginning their yearly festival. Space would entirely fail me to recapitulate the smaller things which go to make the groups complete. Of hardy Orchis and Day Lilies—to Scotchmen always suggestive of the Ettrick Shepherd and the old man and his bonnie Nannie—and Welsh Poppies drooping their yellow heads in the shade, and lifting them again to woo the returning sun, or those with blooms of glowing crimson or scarlet, with petals like crimped satin; but, oh! so quickly past. Satin reminds one of the white Polemonium, prettier even than the Sisyrinchium of the earlier months. The Polemonium Richardsoni, also now in great beauty, globular clumps of light blue. Here we come to the New Zealand Daisy, with starry blooms, white, rose, and pink; there to a broad mass of *Ourisia coccinea*; here to the soft violet *Pentstemon procerus*. A little way we find a mass of soft rose blooms (*Saponaria ocymoides*), and just behind the brilliant double *Lychnis viscaria*, and further on the showier single form of the same. The peculiar blue *Ajuga genevensis* is contrasted with a *Mimulus*, and the *Mimulus* nestles beside a bunchy *Geranium*. These spikes, so like white Roman Hyacinths, are the white *Lychnis viscaria*. That flag-leaved plant, with half a dozen large blue flowers on each spike, is *Iris pallida*. We smell it, and it is aromatic to a degree. These handsome plants of the same species, with shaded flowers of white or lilac, blue or purple, are the English Iris. Here are *Alstroemerias* just beginning their annual feast of beauty, with glorious bunches of the species aurea; there are *Tradescantias* of various sorts; this lilac upright plant the beautiful *Erigeron*; this more upright still, and only a little darker, *Stenactis speciosa*. We miss here the Foxglove, but we shall find it nestling at the base of shrubs, with Hollyhocks and Columbines, or companying with Lilies among Rhododendrons. There we also find the Everlasting Pea rambling over a fallen stump, or with Hop and Honeysuckle hiding the nakedness of some dead shrubs. That mass of grey-green foliage, topped with feathery spikes of white, standing isolated on the grassy lawn, is *Spiræa Aruncus*. Yonder a group of the common *Aconitum*, and there a specimen of the species *Lycotomum*, with its spikelets of delicate yellow.

Every cranny on this old wall is packed with the little creeping *Linaria* (Toadflax), and wreathed in sweet disorder with *Clematis montana*; while here and there a tall *Verbascum* is sending its grey shoots skyward from the tangle, and Snapdragons, yellow, red, and many-coloured, enliven the living picture. I might catalogue the flowers we missed—Byzantine Gladiolus and the satiny-flowered "Bride"—clumps of darkest crimson—the dwarf Sweet William, bronzy *Heuchera*, or Fern-like *Thalictrum* and Tansy, or *Hemerocallis*, with leaves like lawn, were the green edges wanting, spotted *Pulmonaria*, or yellow-striped Iris. But I stay—all are common flowers, but all are lovely.—SYLVANUS.

VINES BLEEDING.

VARIOUS theories and experiences are recorded in the Journal regarding this subject, and it may be safely said that a great diversity of opinion exists regarding the causes of bleeding in Vines. "In a multitude of counsellors there is wisdom," and no doubt the more opinions and experiences are recorded the better. My experience has been that bleeding has occurred in Vines in the most diverse circumstances. For instance, in one case, Vines with the roots all inside, which are pruned early in autumn, never fail to bleed when started, though the wounds made in pruning have at least three months to heal, and the wood every year is as hard and well ripened as can be. The border does not suffer from excess of moisture, indeed it is rather too much the other way. But the more the Vines in this house bleed the stronger they seem to grow, which is

strange when one reads, that according to eminent authorities, bleeding is very weakening to the Vines. Then again, another house in which the Vines are planted so that the roots are both inside and out, and which has a border that from its situation is always very damp, even inside, which only gets what is given it, and is not exposed to the rains of heaven, shows almost no signs of bleeding, though only pruned about a month before being started again.

The Vines in this house though healthy and strong cannot compare with those in the first-mentioned house which bleed so much. In fact, under all conditions of borders I have seen Vines bleed very profusely; and, again, at other times bleeding has sometimes, when it might reasonably have been expected to occur, been absent. That any hard-and-fast rule can be laid down regarding its appearance or non-appearance seems impossible.

Styptics when carefully applied are effectual in preventing bleeding, but in the cases mentioned the Vines have not been so treated for some years, as experience seemed to teach that the Vines were quite strong enough in spite of the bleeding, which according to some is so injurious. The very latest Vines which are started almost immediately after pruning have styptic applied, but I think even this might be dispensed with.

Unnatural as it seems to be that no injury should be done to Vines by the loss of so much sap, it appears that as much can be said on the one side as the other, and experience also lends its aid to make a decision on the question well nigh impossible. Certain it is that Vines which bleed profusely every year can be pointed out as examples of strength and fruitfulness. It is desirable that experience should be recorded without the writers absolutely taking in hand to assert that their special theory on the matter is the right one. Dogmatic assertions that so and so does so and so, cannot obtain in regard to Vines bleeding. Experience teaches that the subject should be approached in a spirit of mutual inquiry and consultations, and not in a spirit of self-assertion and contradictory effusion.—S.

Mr. WAITING's first statements on this subject were plain, it is true, but is it unjustifiable to ask for proof of statements which, to say the least of it, are open to dispute, and which he, instead of proving, has gone far to disprove? In his first notes he says water is the cause of Vines bleeding; now he says that if the wood be properly ripened before pruning they will not bleed. Surely Mr. Waiting has placed himself in a dilemma, for according to his theory water will not cause Vines to bleed unless the wood has not been properly ripened before pruning; hence improper pruning and not water is the cause of Vines bleeding.

But what of his next statement, coming from one who gives advice, to think more "pruning is an evil." May I ask from what point of view is it so? Mr. Waiting seems here to be reasoning from false premisses. Even if unskilful pruning be one of the causes of bleeding, yet it does not follow that pruning is therefore an evil. Perhaps Mr. Waiting had better take the advice he gives and think more, and if he was also to read more carefully he might find many questions in my notes to which he has given no answer. Before bidding farewell to Mr. Waiting I would just remind him that it takes more than nine bunches 13 inches long to form a chain of 11 feet.

Since I have taken objection to Mr. Waiting's theory in regard to Vines bleeding perhaps there are some ready to ask if I have any better theory to offer. In reply to such I will offer one or two suggestions. I believe that bleeding arises from many different circumstances or combinations of circumstances. The wood improperly ripened is perhaps one of the greatest causes, and great care should be taken during summer and autumn to see that laterals are kept well stopped-in, so that all the light possible may be admitted to help to ripen the wood. Pruning too early or too late will also tend to have the same effect. If the border has been allowed to become dry, and is then given a thorough drenching of water and little fire heat to dry the house, this will also tend to stimulate bleeding. These, with many others, are the causes, but of no one separately can it be said that it is "the" cause.—JUSTITIA.

Mr. WAITING has proved quite enough for me. If powdered alum is so effectual I should have thought he would have used it for his own Vines that bled to their injury, for it seems incredible to me that any practical man should risk the loss of his crop from severe bleeding when the simple application of alum would have stopped it. The fact is Mr. Waiting appears to have got out of his depth on this subject, and he changes or modifies his opinions every week. Mark his statement now—that "Strong Vines bleed because they are full of sap," and weak ones because of "their inability to appropriate the excess of moisture." Wherein lies the difference in the two cases, and how could any Vine appropriate an "excess" of anything? Mr. Waiting's statements indicate a confusion of ideas on the subject.—NON BELIEVER.

THE MARSH MARIGOLDS.

THIS is a small family of plants, all of which are great lovers of water, but yet not aquatics. They delight to have their roots in the water and to spread their branches and brilliant flowers to the breeze, and are found naturally in marshy boggy places or on the margins of running streams or lakes. This will at once teach us how to use them in the garden, and many an ugly pond may be made attractive by the judicious use of these and other bog plants; in fact, such spots may be turned into an ever-changing picture with but little trouble or expense. There the dragon-flies and butterflies will come and disport themselves amongst the beautiful flowers, enriching the effect with their quaint

forms and splendid colours, whilst the chirp of the grasshopper and the soft little song of the sedge-warbler all combine to make us exclaim—

"Oh, Fortune! only bless me thus, 'tis all I ask below.
I do not need the gold that serves for luxury and show;
A quiet home, where birds will come, with freedom, fields, and trees,
My earliest hope, my latest prayer, have coveted but these."

There is little or nothing to add respecting the Marsh Marigolds. Planted in such places as we have already described, all that will be necessary is to see that they do not crowd out any less robust-growing plants, or that others do not crush them.

Caltha palustris.—This fine plant is commonly known as the Marsh Marigold, and more rarely by the name of May-blobs. The small unopened flowers are sometimes pickled and used as substitutes for capers. It is a stout erect-growing plant, with hollow stems and entire kidney-shaped leaves, which are toothed on the edge and bright shining green in colour; flowers large, rich golden yellow. It attains a height of about 2 feet, and commences to open its blooms in the month of April, continuing in favourable seasons in full beauty into August. Native of Europe, North America, Western Asia, and takes first rank in our British flora.

C. palustris flore-pleno.—In no respect different from the normal type, saving that the flowers are double, which to those who are partial to these forms is a great acquisition, and there can be no doubt it is very showy and effective. Britain.

C. palustris flore-pleno monstrosus.—The flowers of this form are very large, exceedingly double, and bright golden yellow in colour, quite distinct from the preceding. Britain.

C. polypetala.—A species I have not seen. It is described as a very fine showy plant, growing upwards of 18 inches high, and producing large golden-yellow flowers, which measure upwards of 2 inches in diameter. Caucasus.—W. G. T.

VICTORIA SPINACH AND EARLY NANTES CARROT.

THE demand for Spinach in most establishments renders frequent sowings through the summer months imperative in order to maintain a supply, and this from drought and in shallow soils is of a precarious character. As the ordinary Round or Summer is so prone to run to seed without forming much leaf, and this being the edible part of the plant, any addition thereto is of consequence. This we have in Victoria or Improved Round, which has leaves fully twice the size, and the plant remains fit for use quite ten days longer. It is a valuable acquisition, and is sent out by Messrs. Veitch.

EARLY NANTES CARROT.—This is a great improvement upon the Early Horn, and is a very desirable kind, coming into use quickly, being very little later than French Forcing, the roots being larger than that variety, and though somewhat stump-shaped are longer than Early Horn, the shape being good, and the colour bright red and regular; but the chief characteristic of this Carrot is the smallness of its core, which enhances its excellent quality, and the flavour is mild. It is the best of early Carrots.—G. A.

THOUGHTS ON CURRENT TOPICS.

I DON'T think I should have either troubled myself or the readers of the Journal this week with any mental cogitations, but for the feeling that had I kept my "thoughts to myself" "Non-Believer" might consider me discourteous and himself neglected.

I AM emphatically a man of peace; he, seemingly, a man of war. He enjoys a tilt with the pen, evidently, and if he does not pride himself on his 'euteness my "thoughts are inaccurate." His style I rather like, the more so as it is not borrowed, but a hybrid of his own raising—a cross, it may be timidly suggested, between Carlyleism and Thackerayism—not quite rugged enough for one, nor delicately pungent enough of the other; still it is lively, and that is something in this dull and prosy era of literature.

ON reading the note of "Non-Believer" on page 491—a perfectly fair note by the way, and to which I have not the slightest objection—I felt a little muddled about the "old" and "new" systems of Vine-pruning, as to when the old one expired and the new was born. There ought to be dates, I think, to such important events, solemnly recorded and jealously preserved in the archives at South Kensington, as that I think I have seen described as the "head-quarters of horticulture in this country."

THEN, again, I feel a difficulty in comprehending the point of departure between the two systems. The question seems to resolve itself into one of figures, but unfortunately they have a shifting tendency. I thought it slightly hypercritical to cavil between "8 and 9 feet" and "12 feet," as the proper length to prune Vine rods, and I think so yet. What is the exact and orthodox length of the "new" plan and the extreme limit to which the "old" is restricted? Until that is defined criticism

must degenerate into a wordy wrangle, of which, perhaps, this note is an example.

THEN as to the exact date of the origin of the "new" plan of leaving, say, 12 feet of rod. It appears I went too far back to prove its long existence by citing 20-foot-long rods thirty years ago. That is quite a "new plan" of objecting, certainly (going too far back to prove something old), newer a good deal than the "new plan" of Vine-pruning; but let that pass, and I will come nearer for an example. In 1870-71 the so-called "new plan" was followed in a range of vineries upwards of 400 feet in length, the young canes having been left from 6 feet to 12 feet long, according to their strength, at the first pruning after planting. How will that more modern date suit?

As to the late Mr. Pearson's work and opinions, nothing can be gained by discussing them, and they certainly were not fully declared in his concise little book. This I happen to know by having had the privilege of more than one personal discussion with the deceased gentleman, and I am hence able to record something of what he both thought, said, and did without gathering my material for "history" from a book.

THEN there remains the tremendous question as to the originator of the new old system. I am quite unable whom to think of with the object of according whatever credit may be due. I am quite sure it does not belong to me, for the long rods were in vogue to my positive knowledge in 1850; the grower of the Vines referred to in 1871-1872 made no claim to the discovery; "A Kitchen Gardener," I think, has not entered any claim, nor have we any evidence that "Non-Believer" has done so. I trust we are none of us so weak as to rely on a phantom for our fame, and to spend our time in tilting at windmills.

I AM much obliged to "Non-Believer" for affording me materials for a few notes, and I shall now be quite content for him to go on non-believing.

MR. LUCKHURST has honoured me with notice, and in an able elucidatory communication makes out a very good case in favour of converting espalier fruit trees into palmette verriers, and has shown how well the spaces can be occupied between the shortened trees by vertical or diagonal cordons. I am not the person to find fault with such trees, nor should I like to see some old-fashioned espaliers which I have often pruned and gathered bushels of fruit from shortened and "turned up" and Frenchified, however excellent the new method may be. Trees with branches 18 feet long, as straight as gun rods, studded with spurs and roped with fruit, are not to be lightly transformed. That is my whole contention. Leave well alone; but trees showing signs of collapse of the lower branches can no doubt be remodelled advantageously in the manner indicated.

I AM quite unable to admit the necessity of spurs a foot long on espalier Apple trees, and I think the advocacy of such may have a tendency to lead to that very evil of overcrowding which your correspondent has warned against so effectively. That the practice is safe in Mr. Luckhurst's hands I should not think of questioning, but all owners of fruit trees are not in a position to bestow on them such "watchful and intelligent" care as he does.

I OBSERVE spurs 6 inches long are referred to as "puny," and am asked how many Apples nearly 6 inches in diameter I would leave on such spurs. I would leave one, and be thankful. If more of that size can be developed on long and lanky spurs I should like to see them. I am asked by Mr. Luckhurst if I have ever seen a cordon. I have answered in the affirmative, and recognised the value of such trees. May I ask your correspondent if he thinks the wonderful Apples and Pears that have won the chief prizes of late years at Hereford and other great exhibitions have been produced on spurs a foot long? I am strongly of opinion that the spurs from which they were gathered were not half that length; and I think very loudly that trees well furnished with 6-inch spurs will bear as much fruit as can be matured of first-class size and quality, and a good deal more if all the blossoms set. Where, then, is the advantage of longer spurs?

WHILE on the subject of fruit trees, I think "H. J. H." (page 488) gives a good hint on summer pruning. This practice is often deferred too long, then carried out too severely. More than once I have seen mistakes made in shortening the growths of Pears, Apples, and Gooseberries to two or three leaves, some of them imperfect, as is often the case; and a safer and better

plan, as a rule, is to leave five or six leaves, doing the remainder of the shortening at the winter pruning. Severely shortening the growths in summer after much crowding has often been followed by the shrivelling of the few leaves that were left, when the weather has been dry and the sun hot. The trees have then decidedly not been benefited by summer pruning.

DOCTORS appear to differ on the measures to adopt to prevent the scalding of Grapes—at least on the question of temperature. "Keep the house cool," says "S." (page 485). Does he mean cool at night as well as by day? for some competent persons rather advise that the night temperature be somewhat increased, to prevent the condensation of moisture on the berries. The colder the fruit is, the greater the condensation must be; then unless very early and gradual morning ventilation is carefully practised, the evaporation from the fruit is excessive, which necessarily cools the surface and a collapse occurs. Is there not something in that theory? I am inclined to think so. The worst case of scalding I have seen was in a vinery without fire heat during a period when the nights were unusually cold and the days hot. Had there been less difference between the night and day temperatures, the probability is that the evil would have been less pronounced. Preventing a very high temperature during the day, and a very low one at night is, in my experience, advisable, with always plenty of foliage; sufficient, as your correspondent says, to "cover every inch of roof." Acting on this principle about the stoning period, I have never been troubled with scalded Grapes.

A "WRINKLE" in baffling the Onion maggot is, I think, imparted by Mr. Henry F. Moore on page 484. It is a fallacy to suppose that salt, lime, and soot dug into the ground prevent the attacks of the maggot. No such mixture that can be safely applied will kill the parent of the grubs in its chrysalis state. The maggots do not crawl out of the ground and attack the plants. The attack is from the air, the flies depositing eggs on the leaves, and the maggots resulting find their way to the ground and enter the Onion just below the surface, where the neck of the incipient bulb is blanched. They never enter the green leaves or stem; and here comes the "wrinkle," the "young Onions slightly earthed up are protected from attack." This is worth trying, but to be fairly tried the slight earthing should be done in good time. Transplanted Onions are not often seriously attacked. Is it not because the vulnerable part of the plant is inserted in the soil?

WORTH remembering, I think is Mr. Harding's remedy for the fruit form of the Cucumber disease—"increase of fire heat with less atmospheric moisture." This disease was the most prevalent during the wet and cold summers that prevailed two or three years since, and with warmer and drier seasons its virulence appears to have subsided. Several years ago there was a great outbreak of this disease, and the seasons then were inclement; when the summers were warmer it practically vanished. It is a terrible scourge, and the method of checking it above indicated is at least worth a little thought by those who may be so unfortunate as to have to combat the destructive visitant.

BURIED in the middle of a paragraph on page 483 is a brief but merited tribute to the effectiveness of Delphiniums in gardens about midsummer. "When the spikes from 6 to 7 feet high develop themselves, how grandly gay the garden is," says "D., Deal." "Grandly gay" indeed are these noble plants. I have had the pleasure of growing them largely, and the towering masses, some of them 9 feet high, and of the most charming colours, are splendidly imposing. Grow in rich deep soil, thin out the stems, secure them to stakes, mulch the soil over the roots, give liquid manure copiously, and see what good varieties of Delphiniums will do. They will astonish those who have been content to grow them on the let-alone principle, and will command admiration.

THE notes on Stapelias take me back in memory, and directed my thoughts to many good and curious old plants of forty years ago. Vineries were heated by flues in those days, and good Grapes were grown. On the flues were Cactuses and Stapelias, the former trained up the back wall of a house 50 or 60 feet long, which in the season of the plants' flowering was a blaze of beauty such as would have gladdened the eyes of Mr. Castle, who seems to have a weakness—or shall I say strongness?—for these lately neglected plants. The Stapelias were not gay, but remarkable. We garden boys always called them Toadflowers, from the fancied resemblance of their colours to the markings of toads; also perhaps because both were considered in about the same degree

repulsive. I have known persons admire toads, caress and fondle them, but I never remember anyone expressing delight at the fragrance of *Stapelias*.

"Now we have got to toads it is time to stop," I fancy I hear my readers muttering. But blame not me for this infliction. I have simply been led into it. The real authors of these thoughts are "Non-Believer" and Mr. Luckhurst; but for their allurements I should have been this week, as I shall be next, a silent—THINKER.

DISEASE OF GARDEN ANEMONES.

GARDEN Anemones are very subject in April, May, and June to the attacks of a destructive parasitic fungus, a parasite, which in this case is perennial—that is, the spawn or mycelium of the fungus is always within the plant invaded, either in the tissues of the perennial rootstock or in the growing stem and leaves. The pest, which does not die with the dead leaves, is probably familiar to every grower of Anemones, and

or chamber is (or rather should be) divided into four. This specific name is a very bad one, for the mouth of each cup, as may be seen at B, is generally lobed and torn in a very irregular manner, seldom or never presenting four parts only.

The history of the fungus of Anemones is, as far as it is known, a simple one, and can be readily followed with the use of a microscope. We will therefore first take a very small fragment of a diseased leaf, place it under a power which magnifies fifty diameters, and look at the little fungus cups and dots on the lower surface. One yellow pustule will answer for all. Under the microscope each yellow spot or pustule is seen as a deep little cup, as at B, with frayed edges. The edges, which in the mature examples turn outwards, at first covered over the open part of the cup when it was in a ball condition. As maturity is reached the ball bursts and the frayed edges turn back as illustrated. The investing cup itself is composed of a single thickness of minute cells or bladders packed side by side like the cells of a honeycomb. These constituent cells or bladders are shown in the frayed edges. The cup itself is not an empty one, but, on the contrary, is full of microscopic globular balls, like minute grains of yellow pollen; these bodies, also shown in the middle of the cup in the illustration at B, are the spores or reproductive bodies of the fungus, roughly answering to the

Fig. 116.—Anemone diseased.

during the last two years it has been unusually prevalent and virulent. Its effect on the host plant is often to promote an extraordinary but spurious appearance of luxuriance; instead of a few leaves being produced an enormous crop of healthy-looking leaves with long stems spring up from the ground, in too many instances accompanied by no flowers. Our illustration at fig. 116 shows a plant greatly reduced in this condition.

No phenomenon is better known in plants and animals than a spuriously healthy appearance preceding disease. The greenest and healthiest Potato plants are often the first to fall before the murrain, and corn-mildew and bunt often appear in their worst form in plants of apparently the greatest promise. Unusually fine and large Pears often drop from the trees full of larvæ, and in the human family a bright healthy colour is often a forerunner of consumption and death.

If a leaf is gathered from an Anemone suffering from disease, and the under surface is examined, it will be found, as at A, fig. 117, covered with a vast number of little yellow dots or cups, accompanied by an equally large number of minute black spots, the latter too small to be seen in the natural size illustration at A.

The name of the fungus is *Æcidium quadrifidum*, D.C., and we have not hitherto seen any published illustration of it. The name *Æcidium* is one form of a Greek word (it should properly be written *Ecidium*) meaning a little chamber—a very appropriate name, as we shall see further on; *quadrifidum* means that the mouth of the burst fungus cup

Fig. 117.—*Æcidium quadrifidum*.

seeds of flowering plants. The spores of course, like ovules, are female. Three of the black dots are also shown—one is marked at C. These are glutinous little spots, termed by botanists spermatia, or male bodies containing male fertilising atoms named spermata, roughly answering to the pollen of flowering plants. Some of the little round spores out of the *Æcidium* cup will be seen sticking on to the little black glutinous discs, or on the fine spermatic threads growing out of the discs at C.

A difference must be noted here between the habit of the fungus and a flowering plant. In the latter, as every observer knows, the pollen (male) is littered out of the anthers on to the stigma (female), but in the fungus the spores (female) are littered out of the *Æcidium* cup (female) on to the top of the spermatium (male). In the flowering plant the pollen is free and the ovules fixed, in the fungus the ovules are free and the pollen fixed. This is not given as a rule without exception, but it is a rule which holds good for the fungus we are now examining.

The fine lines seen outside the frayed edges of the *Æcidium* cup represent the lines of junction of the cells which go to form the lower cuticle of the Anemone leaf. Here and there little openings occur, as in the three shown near D. These openings are the stomata or organs of transpiration of the plant; through these little orifices the plant exhales water in the form of vapour. In dry weather the little openings keep closed, so that the plant may not perish by losing all its moisture in the form of vapour, but in damp weather the little mouths stand

elastically wide open, so that the plant may be benefited by the damp air.

It commonly happens that when fungus spores germinate on the under surface of a leaf in humid weather, that the fine spawn threads from the spores find out these mouths of transpiration, and so get inside and amongst the tissues of the leaf by the open doors. Sometimes the thread of the fungus is of such a nature that it sets up putrescence in its course of growth. This is the case with the spawn of the fungus of the Potato disease; it gets inside the leaf by the little open mouths or organs of transpiration. It then not only lives inside the leaf and sets up putridity in its progress of growth, but it sends out new spawn threads from the inside of the leaves through the mouths outwards. This process soon chokes up all the stomata and reduces the stem as well as the leaves to a putrid mass.

The stomata of the Anemone are somewhat small, and the spores of the invading fungus somewhat large, and it is supposed by some observers that the spores on germinating on the surface do not usually enter the Anemone leaf. This point is a hotly disputed one amongst botanists, but we need not enter into controversial matters here.

The *Æcidium* cups and the male organs termed spermagonia are embedded in the substance of the Anemone leaf, and it is desirable to see them both in section. For this purpose a leaf must be cut in two with a keen lancet, and the cut must be made through both *Æcidium* and spermagonium. When the leaf is divided, a slice, or rather film of inconceivable thinness, must be sliced off the cut surface and transferred to a slip of glass. If the slice is successfully made we shall see the fragment as shown in the lower illustration of fig. 117. The lower surface of the leaf is shown at E, and the upper surface at F. The epidermal cells top and bottom are colourless, not green. At G G two organs of transpiration are shown, both open and leading to the intercellular spaces between the constituent cells of the leaf. Between the two letters G G an immature *Æcidium* cup may be seen embedded in the leaf—a "little chamber"—full of spores or seeds—hence the name. Between E and G an immature dark-coloured spermagonium is seen embedded. At H a mature *Æcidium* cup is illustrated; the cup has burst through the lower cuticle of the leaf, thrown back its frayed edges right and left, and the spores are hanging in chains from the open mouth. At J a ripe spermagonium is shown also bursting through the epidermis of the leaf. Attached to its glutinous mouth and protruded spermatid threads some of the shed spores from the *Æcidium* cup may be seen. It will be observed that the leaf near H is considerably thicker than at E, F. This extra thickness, or hypertrophy of the leaf tissues, is a common after result of the attack of parasitic fungi. The reader should remark that each *Æcidium* cup is made up of an investing membrane of one series or stratum of transparent cells, and that the presence of both *Æcidium* cups and spermagonia cause the tissues of the leaf to become corroded and blackened within.

It is now only necessary to take a single spore from a cup and use the highest powers of the microscope for its magnification. If we enlarge 1000 diameters we shall see the yellow spore, as at K, full of granular protoplasm, or vital formative material, and more or less studded by the sticky male dust from the protruded and broken-up threads of the spermagonium, or male organism.

The *Æcidium* cups and the spermagonia both arise from the same spawn or mycelium within the leaf. The mycelium forms knots near the lower surface of the leaf where the constituent cells at E are looser and larger than the small and compact ones above, as at F, and where the little vertical strengthening palisade cells seen just under the transparent stratum of the upper leaf surface at F are absent. The upper surface of the leaf at F is too firm for the development and bursting of the *Æcidium* cups and spermagonia.

The *Æcidium* of Anemone is a close ally of the *Æcidium* or "blight" of Barberry bushes, a fungus which is supposed by some observers to be the cause of the red rust and black mildew of corn. The fungi of rust and mildew are termed *Uredo* and *Puccinia*, but no members of these two genera have been yet associated with the *Æcidium* of Anemones. All that is known of the fungus of Anemone blight (*Æcidium quadridum*, D.C.) is that the phenomena we have described are repeated year after year on the produce of the same rootstock from the perennial mycelium within the tissues of the perennial host plant. There is no remedy for such a disease; the only plan for the destruction of the fungus is to root up and burn all infected plants.—W. G. SMITH.

SPECIAL SOCIETIES—EXHIBITING.

MUCH has been published under this and somewhat similar headings in the *Journal of Horticulture*, yet we are not much nearer to the solution of one or two knotty questions than at the commencement of the discussion. In the course of the correspondence a few proceedings have been brought to light, that to say the least were not expected. Now the question is, Who are those who lie under the imputation of trading in a certain class of plants of which they have made a speciality, and yet take many prizes as amateurs? Why should there be any ambiguity about the term "amateur" as distinguished either from professional gardeners or growers for trade purposes? Separate classes are generally provided for each branch of the profession. Anyone managing their own gardens, only receiving occasional assistance, are termed amateurs, while gentlemen constantly employing a qualified gardener with or without further assistance have sometimes classes specially provided for them, but otherwise they must compete with professional gardeners. The nurserymen or those who grow principally for sale have their own classes,

or meet the others in those "open to all" only. This is plain enough surely, though it does not appear to be understood by all, especially those who wish to win the lion's share of prizes.

If it is not thought desirable by the framers of the schedules of the Royal Horticultural, Royal Botanic, and National Auricula and Carnation Societies to separate the amateurs from professional gardeners, then I hold that traders or those who market their surplus with their superior advantages over the ordinary amateur and professional gardeners ought not to compete against the two latter, but should meet the nurserymen or growers for sale. We hear of no infringement of this well-understood rule at either of the exhibitions of the two first-mentioned Societies; and this brings me to the most important and seasonable subject matter.

It will be observed the arrangements of the schedule of the National Carnation and Picotee Society prevent exhibitors of twelve blooms of Carnations and twelve Picotees from competing in the classes for six Carnations and Picotees respectively—a commendable proviso intended, I presume, for the encouragement of beginners. Now, I should be glad of a few plain answers to questions I propose to put in connection with these classes and Carnation showing generally. In the first place, who is Master Stanley Dodwell, Oxford, who at the 1882 Meeting was first and second respectively in these same set-apart classes, and first in both the classes last year? What is his age and occupation? We are gradually approaching the date of the next Carnation Show, hence the necessity for explanations. Perhaps replies to a few plain questions may tend to smooth matters somewhat, and decide waverers who may wish to compete, but who hesitate to do so under the circumstances.—NO AMATEUR.

[We have made inquiry into the question which has been asked by "No Amateur," and we are informed by an Oxford correspondent that Master Stanley Dodwell is the grandson of Mr. E. S. Dodwell, Joint Honorary Secretary of the National Carnation and Picotee Society, that his age is "about seven years; but it is immaterial whether his age be six, seven, or eight years, as he is a youth not advanced in years beyond the stage generally denominated the school-boy period."]

HARDY LADY'S SLIPPERS.

WE have under cultivation to-day in many instances a vast number of hardy terrestrial Orchids, all more or less beautiful and interesting, while many are really handsome, and may proudly vie with rare tropical species. The latter can only be grown by skilful hands and in heated structures, while those to which I shall draw attention may, by following these simple instructions, be grown by anyone under ordinary circumstances, and should in fact find a home in every English garden. Varied (and pretty too) as are our native species and varieties of Orchids, still they fall a long way in the rear when we consider such gems as *Calopogon pulchellus*, *Bletia hyacinthina*, *Cypripediums* generally, and *Habenarias* likewise, which come to us from other parts of the globe. Neither time nor space, however, will allow of my entering into a detailed account of the many, hence it is my intention in the present note to speak of one or two of the most distinct *Cypripediums* or Lady's Slippers.

Recalling the generic name for a moment, the writer is reminded of the vast importance attaching thereto among Orchids generally, not only in respect to hardy species, but to tropical and subtropical alike. In the two last-named instances this genus holds a prominent position, and among the hardy species it stands pre-eminent.

CYPRIPEDIUM ACAULE (Stemless Lady's Slipper).—Why a plant having a stem from 6 to 8 inches high should receive the specific signification of stemless I am at a loss to understand, since that is about the average height of many species from warmer regions. This, however, is of only minor importance when we come to consider its real qualities. It is at once one of the handsomest and hardiest of its genus, and readily distinguished from all other species by the deep fissure in the labellum. When well established the plant attains a height of 6 or 8 inches, the flowers being of purplish rose colour, nearly 2 inches in length. Its culture is simple. It may be planted in a sheltered nook on the rockery—that is, on the lower and damper portions, or fronting a *Rhododendron* bed, or in company with dwarfed American plants of a peat-loving nature. It may also be grown successfully in leaf soil and sand, and as a further proof of its willingness to submit to a variety of soils, it may be well grown in very sandy loam. As a pot plant it is charming, and with the protection of a cold frame or handlight its flowering period may be considerably lengthened. It comes from North America, where it is to be found in plenty, and as with a great majority of collected plants varies considerably in the colouring of the flowers. A well-drained position is at all times indispensable to its well-being.

C. CALCEOLUS (English Lady's Slipper).—In this we have a true Britisher, equalling, and indeed surpassing, many a tropical species. In general excellence, at the same time, it is by far the largest and handsomest of our native Orchids. When well estab-

lished it will attain a height of from 12 to 20 inches, and supporting one to three of its handsome flowers. The predominant colour of the lip is clear yellow, while that of the sepals and petals is of a brownish purple. It prefers under cultivation an aspect similar to that under which it is usually found in a wild state—viz., an eastern one, and should be planted in deep rich loam of a fibrous nature in perfectly drained positions. If a rockery is available, choose a fissure somewhat shaded, and mingle in planting some nuggets of calcareous limestone. The plant is found abundantly throughout continental Europe, and may readily be obtained from hardy plant nurseries. It is, in short, one of those charming hardy garden gems which can be cheaply bought. Thus there is nothing to prevent its admission into all gardens.

C. SPECTABILE (the Noble Lady's Slipper).—This species may fairly claim precedence over all others. While not forgetting such choice kinds as *C. macranthum* and others, I give the palm to *C. spectabile*, since it lends itself so readily to forcing in pots for indoor decoration, and at the same time is so hardy. In its native home it inhabits meadows and peaty bogs, and is readily distinguished from all other members of this family by its bold slipper-like and much-inflated labellum, which varies in colour from delicate rose to rich rosy purple, the sepals and petals being white. When thoroughly established it attains a height of 20 inches, well furnished with broad handsome leaves, terminating with one or more of its lovely flowers. Two-flowered scapes of this plant are frequently occurring, which is in itself a guarantee of great strength, together with its cultural conditions favouring its well-being. The best soil in which to grow this is a deep bed of rich spongy peat kept continually moist, though well-drained, since all the species are most impatient of stagnation. A somewhat shaded position will suit it well, and a liberal dressing annually of decomposed vegetable matter will materially assist in strengthening the plants. This species has of late years been sent over from its North American habitat in great numbers, and no difficulty should be experienced in obtaining strong and fresh roots. This is of great importance, for if the roots are withered and dry, then the chances favour its complete failure; nay, more, its ultimate death. The three species above named are the most distinct of the genus, and the easiest to manage, all flowering during June and July, allowing, of course, a slight margin either way for our variable seasons.—J. H. E.

HORN DUST.

I DO not recollect mention ever having been made in any of the horticultural papers of horn dust as a fertilising agent. Reference is frequently made to those preparations that we are accustomed to call artificial manures, and many of the special fertilisers now before the public are of undoubted value and benefit in growing plants and garden crops generally. Has horn dust fallen into disuse, or is its fertilising value only local? From my earliest recollections of gardening operations it has been in use for almost all kinds of crops. In the neighbourhood of Sheffield it is regularly used by farmers, gardeners, and nurserymen, who no doubt benefit by its application, or they would not continue to use it. On a small scale I have used it for vegetables and flowering plants, and they are always improved by its judicious application.

It is best dug into the ground in autumn and winter, or providing the season is wet, in early spring; it is of too dry a nature to be applied during the hotter portions of the year. Strong loam for potting purposes is improved if it is sprinkled on the turves when stacking them up, time being allowed for its decay. It makes a good dressing for Gooseberry and Currant bushes, spread on the soil in autumn and forked in a few inches deep.

I should like to know the experience and opinion of both professional and amateur gardeners who have used it as a manure. If the Editor would kindly insert any report on this subject, the information thus obtained would be instructive to the readers of the Journal.—J. H. S.

ROSE A. K. WILLIAMS.—You are likely to have numerous communications disproving the inference of "Y. B. A. Z.," page 467, as to the supposed "weak constitution" and want of "stamina" in this glorious Rose, so I will only ask space for a few lines from the Emerald Isle, as a devout worshipper of this empress among so many Rose queens. Your correspondent gives us no hint as to the soil, situation, treatment, or even the locality from which he writes, all of which might be of importance in coming to a conclusion. In fact, there is nothing so variable as the success even neighbours have with the same Rose. I am quite prepared any day to lift my hat to Marie Baumann, but last year she did

not give me the chance; but I afterwards found it was not so much her fault, and this year 'tis different. What would your correspondent think of preparing richly a border by a southern wall for the above twin favourite? I will guarantee, except very different from me, vigorous growth and plenty of blooms.—W. J. MURPHY, *Clonmel*.

THE CUCUMBER DISEASE.

ALLOW me to point out that the details of washing, disinfecting, &c., described by Mr. Harding on page 481, may possibly have had nothing to do with getting rid of the Cucumber disease, because similar plans have been tried repeatedly and have invariably failed. The disease in his case, and all others where it has been conquered, has been stamped out by leaving nothing for it to exist on. Any of your readers troubled with this pest, who will banish all Cucurbits from their premises for four months, as he did, and start again with a healthy stock, will without doubt get rid of the disease, and that is decidedly the best and cheapest way of doing it. This applies only to the gumming disease, of the root disease I have had no experience.—WM. TAYLOR.

A NEW INSECTICIDE—LEMON OIL.

"STILL they come!" may be the ejaculation of someone on reading this heading. Insecticides will soon be as prolific in novelties as garden lists are in new Peas. What do we want a new insecticide for? "Well, have we not Fir tree oil, an excellent preparation, and cannot we use paraffin mixed with an alkali like soap, and also fall back on hot water softened with soap as a cheap and generally efficient means of cleaning plants from dirt accumulation and insect pests?" Still I imagine we have room for another good preparation, and that I imagine will be found in one that was kindly sent to me to try two months ago by Mr. R. Campbell, Oakmore Hall, Northwich. Mr. Campbell has named his mixture "Lemon oil," and we must give him credit for an acquaintance with the constituent parts of his own insecticide; but I should be inclined to believe that the "lemon" bears much the same relation to the killing ingredient therein contained that the too seductive jam does to the medicine, in which the latter is presented to youthful dyspeptics. Lemon oil certainly smells of Lemon, but there the likeness ends.

I have been experimenting with it for two months, the last experiment being to put to rout a horde of ants which too hastily assumed that a crop of Peaches had been furnished for their own particular delectation. I must confess to have been repeatedly beaten by these wise and indefatigable insects, who, no doubt, have increased in wisdom and the world's ways since the days when King Solomon lifted them out of obscurity. I am certain, however, that none of them, not even their greatest living philosophers, know anything about Lemon oil. The main branches of the trees were merely rubbed with a solution of the oil, and the ants have one and all retired; whether to debate on what this wonderful substance can be, and to form some means of overcoming their dislike to it, or whether they have taking a "scunner" at Peaches, I cannot certainly say, but I think hardly for the latter reason. Before the episode with ants the complete efficacy of the Lemon oil as a destroyer of bug, scale, green fly, &c., and as a means of cleaning plants had been established. I can only hope that Mr. Campbell will see his way to put such a desirable insecticide in the hands of the public.—R. P. BROTHERSTON.

FANCY PANSIES.

I HEREWITH enclose a gathering of Fancy Pansies, and wish I could induce you to say a word or two in their favour. The blooms enclosed are a fair sample of the flowers obtained from a packet of seed procured last July from Messrs. Paul of Paisley, which was sown as soon as obtained, and the seedlings transplanted in the beds at the end of September. For the last three months or very nearly so the plants have been a mass of bloom. Many of the flowers were much larger and brighter in colour than those sent which, owing to the heat and drought we have had, are now past their best, and the plants must shortly make room for the summer bedders. I do not know of any flowers which for the same amount of cash and trouble will repay so well as these. If you think this note worth a place in our dear old Journal it may be the means of inducing others to grow these beautiful flowers, which is what I wish, for watching and comparing them has been a great pleasure to me.—W. WALLACE, *Yardley*.

[We can say a very good word in the favour of the flowers sent. We never saw finer from a packet of seed, and the plants have been admirably grown.]

HALF-HARDY BULBS.

IT is strange that these beautiful plants are so much neglected in these days. It cannot be that their beauty is not appreciated, for when well grown they are invariably admired. Is it because their culture is not understood? This seems to be the most probable reason, and even their would-be friends are not adopting the best means of rendering them more popular or their culture more satisfactory. Some time ago I read paragraphs in the gardening papers speaking in most laudatory terms of a bulb border that was to be established at Kew, and when on a visit to the Health Exhibition last Thursday I found time to run down chiefly with the object of seeing this border. My journey was, however, a disappointing one, for except a clump or two of *Gladiolus byzantinus* there was nothing

of much value or beauty, and several of the plants had a very unhappy appearance. I have tried growing many Cape bulbs out of doors, but with a small share of success, and it seems to me that such trials are merely a waste of money and labour. During the last two or three years I have given up all attempts of the kind, as I find I can grow these charming little plants to much better advantage in a cool house, and probably many persons who see the Kew border will come to the same conclusion.—R. T., *Sussex*.

At a General Meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, William Haughton, Esq., Treasurer, in the chair, the following candidates were elected Fellows—viz., Mr. William Edmund Callaghan, Mrs. Callaghan, Mr. Thomas Mansel Franklin, Mrs. Jennings, and Mr. Harry Loveday Pike.

— PRESENTATION TO MR. B. S. WILLIAMS.—At the recent Show of the South Essex Horticultural Society Mr. B. S. Williams of Upper Holloway was presented with a pair of silver candlesticks and inkstand as a recognition of the assistance he has rendered the Society by exhibiting collections of plants, judging, &c.

— A CORRESPONDENT writes that "The ninth annual trip of the EMPLOYEES OF MESSRS. R. SMITH & Co., St. John's Nurseries, Worcester, was celebrated on the 17th, when 460, including wives and friends, left Shrub Hill Station at 4 A.M. by special train for Portsmouth, arriving there about 8.30 A.M. After the inner man had been satisfied the excursionists dispersed in different parties to visit the various places of interest—viz., Nelson's ship, the 'Victory,' the training ships 'St. Vincent' and 'Duke of Wellington,' and the dockyard. After the above-mentioned sights had been seen, the parties made their way for Southsea pier, where a special steamer, the 'Heatherbell,' was chartered to convey them round the Solent, starting from the pier at 2 P.M., passing the forts, Ryde, Osborne House, Norris Castle, and Cowes, returning by the Hampshire coast and arriving at Southsea pier at 4.30 P.M., the remainder of the day being spent in Portsmouth. After a very enjoyable day the excursionists left Portsmouth at 7.30 P.M. and arrived in Worcester at midnight. Great credit is due to the railway officials for their courtesy; and the working committee, Messrs. Aylett Cox, and Harber, the respected foremen of the firm, deserve the warmest congratulation of all concerned for the pains taken by them to render the holiday a success, and one not readily to be forgotten."

— MR. MCINTOSH'S fine collection of RHODODENDRONS has been a source of great attraction of late, and the garden at Dunevan has been admired by many visitors. The beauty of the shrubs is over now, but one or two late varieties are worthy of notice, because they are both late and beautiful. Very fine after most others have faded is Lady Annette de Trafford, a rosy-lavender, with a distinct and bold blotch, very effective and floriferous. Concessum, a warm rose, with fine flowers and symmetrical trusses, is also quite fresh and charming; while Maculatum superbum and Marchioness of Lansdowne are producing their attractive flowers freely. Rather late, but perhaps not quite so late as those named, Apology is one of the most conspicuous and beautiful, and should have a place in all collections.

— THE LILIUMS, which are such a fine feature of the same garden in summer, are very promising, many clumps rising vigorously, and from 6 to 8 feet high, amongst the Rhododendrons, particularly strong, perhaps, being *L. auratum platypetalum*. In a round bed several plants of *L. giganteum* are flowering, and their noble spikes and immense cordate leaves are highly imposing. These plants have had the protection of parasols, which have been most effectual, as without some such aid the flowers could not have been in the condition they are now, as is evident by the frost-bitten leaves towards the base of the plants, and which were not so well sheltered by the protectors. In the Lily house *L. martagon album* is lovely, *L. Szovitzianum* charming, *L. Hansonii* attractive by its waxy bells, and a seedling from *L. Washingtonianum* striking by the richness of its spots.

— IN the grounds the CONIFERS are worthy of especial note.

They are not numerous, but a few of them are perhaps unequalled in Britain. The magnificent specimen of *Cupressus Lawsoniana erecta viridis*, it may be safely said, is the finest example of this distinct and beautiful Conifer in this country, approaching, as it does, 30 feet high, and admirably furnished. Near it, and still taller and equally symmetrical, is *Picea magnifica*, beautiful in its silvery sheen. *Abies Albertiana* cannot be overlooked. There are persons who consider this splendid Fir identical with *A. canadensis*, but the delusion will be at once dispelled by an inspection of the grand specimen in question, about 70 feet high, which is altogether more massive and handsome than the slender and graceful Hemlock Spruce. That Mr. McIntosh's protracted illness is regretted by all who know him goes without saying; still it is gratifying to be able to state that he can occasionally at least walk round and enjoy his much-cherished garden. His able gardener, Mr. Taylor, will be obliged by being informed of the best remedy for mildew on Grapes. He has tried many so-called specifics, but found them wanting; and although not many men are more competent "all round," he is not above learning what others may be able to teach on this subject.

— THE HASTINGS, ST. LEONARDS, AND EAST SUSSEX FLOWER SHOW will be held in the Alexandra Park, Hastings, on Wednesday, August 20th. Prizes are offered in 135 classes for plants, flowers, fruit, and vegetables, and in the leading classes the prizes are fairly liberal.

— *SILENE MARITIMA FLORE-PLENO* is a pretty border or rockery plant, but is best suited for the latter position, as, its growth being of a trailing habit, it droops over and pleasingly clothes any bare ledges or projecting rocks. The flowers are large, full, pure white, and altogether extremely attractive, especially as they are numerous and lasting.

— ON several occasions Mr. W. H. Stacey of Dunmow, Essex, has shown blooms of remarkably pretty VERBENAS, but those he recently had at Kensington were especially fine, and comprised several excellent varieties. Lord Brooke, which was honoured with a certificate, is most effective, of a brilliant scarlet colour, with a white centre, which contrasts strikingly with the body colour. Other notable varieties were Cantab, mauve, Marginata, pink, both with white centres; Harlequin, striped with crimson and mauve; Clown, striped with purple, and Orion, of a fine carmine hue, very bold flower, and large truss. Mr. Stacey has given much attention to the improvement of the Verbena, and it well deserves his care if he can produce such beautiful varieties as these.

— THE QUEEN OF SAXIFRAGAS, *S. LONGIFOLIA*, has been well named. It is one of the most magnificent of the crusted section, closely related to the pretty pyramidal Saxifraga Cotyledon, and still closer to the longifolia of the Alps, generally known in gardens as *S. Hoslii* or *S. elatior*, from which, however, it differs in having much narrower and more numerous leaves. They are arranged in large regular rosettes 6 to 8 inches in diameter. In crevices of overhanging stones they are quite at home, establishing themselves with very little difficulty, growing and flowering with surprising freeness. The flowers are white; they are very pretty on the robust spike. It is propagated easily from seed, which it ripens freely. Native of the Pyrenees, and flowers June and July.

— FEW plants are to be compared to the Carpet Chamomile, *PYRETHRUM TCHIHATCHEWII*, for forming dense carpets in almost any position. As it grows as freely under trees as it does in the open, and seems to be quite indifferent to moist or dry situations, it might be used with advantage for covering bare unsightly places requiring a dwarf vegetation, as it is not without considerable beauty during the summer months, studded with its white-rayed Chamomile-like flowers nearly a foot high; they are useful for cutting, as they last a considerable time in water. It strikes easily from cuttings. A good companion to the above is the *Matricaria caucasica*, known also as *Pyrethrum caucasicum*; it grows a trifle taller, and the leaves are not so finely cut.—M. S.

— THE DARLINGTON ROSE SOCIETY will hold their Exhibition this year in grounds of Southend Park on Wednesday, July 16th, when about £135 will be offered as prizes in nineteen classes, in addition to the two silver medals presented by the National Rose Society for the best amateur's and best nurseryman's stand of blooms. The two most important classes for sixty blooms (nurserymen), the prizes being £8, £6, £4, and £2; and for thirty-six blooms (amateurs), the prizes for which

are £8, £5, and £3. It is a most liberal schedule, and will undoubtedly be well attended by exhibitors.

— THE FORESTS OF EUROPE are estimated to cover 500,000,000 of acres, or nearly 20 per cent. of the surface of the Continent. In British North America there are said to be 900,000,000 of acres of forest in the United States 560,000,000, in South America 700,000,000. The total thus estimated for Europe and America alone is equal to 3,600,000 geographical miles, each containing 736 English acres.

— IT is said that over 500,000 ROSE TREES are annually imported into America from England, France, and Holland.

— A FLOWER POT has been patented in Illinois which is described as so constructed that a quantity of water will be retained in the lower part of the pot, and at the same time air will have access to and circulate around the roots of the plant, thereby promoting rapid growth.

— THAT IRISES rank amongst the best of town flowers is evident by the grand display of them at Alpha House, Regent's Park. For some time the German varieties have been magnificent, now the Spanish varieties are dazzling by the richness of their colours, and these in turn will be followed by the "English," which are just commencing flowering. About five thousand bulbs have been planted, and of other hardy bulbs about thirty thousand. After thus furnishing the garden and adding herbaceous plants from English and continental nurseries, Alpha House, with its beautiful lawn and grand Weeping Ash, the pride of the garden, is, we believe, "in the market;" it will be well if the next proprietor has the same love of flowers as has Captain Patton.

— GARDENING APPOINTMENT.—Mr. Samuel Taylor, late gardener to the late Sir Henry W. Ripley, Bart., Acacia, Rawdon, near Leeds, has been appointed gardener to James Lund, Esq., Malsis Hall, Crosshills, Leeds.

— AT the ROYAL OXFORDSHIRE HORTICULTURAL SOCIETY'S COMMEMORATION SHOW, held at Oxford on June 17th, no less than thirty-six first and other prizes were awarded to the produce of seeds supplied by Messrs. Webb & Sons, the Queen's Seedsmen, Wordsley, Stourbridge.

— ERRATUM.—I would ask permission to correct a clerical error in the beginning of the last paragraph of my "Notes from Bournemouth," which should read "Would be incomplete without a reference being made to Mr. E. White's floral establishment in the Holderness Road," and "the summer and winter garden between the Priory and Cranbourne Roads." The latter belongs to a "company," and is situated at least a mile from Mr. White's place. And "John Lellom, Esq.," should read "John Sellom, Esq."—H. W. WARD.

NOTES ON ORCHIDS.

CATTLEYAS FROM SOUTHPORT.—R. P. Percival, Esq., Cleveland, Southport, has sent us a box of magnificent Cattleya blooms, representing a large number of distinct and handsome varieties of *C. Mossiæ*, *C. Mendeli*, *C. gigas*, and *C. Sanderiana*, the last-named being superb. Cattleyas are grandly grown at Cleveland. The plants are of wonderful strength, and flower proportionately freely, the blooms attaining great size and richness of colour. The varieties of *C. Mossiæ* differ considerably in the colour, especially in the veining of the lip, some being of the brightest gold, and others much lighter. The sepals and petals, too, are in some pale blush, and in others of a deep crimson-rose. *C. Mendeli* is less varied, but the colouring of the lip also differs, and a few are nearly pure white. *C. Sanderiana* is most handsome, one fine spike having six grand flowers with the lips of unusual size and the richest crimson. Mr. Percival has carefully studied the requirements of his plants, and, assisted by his gardener, Mr. Beddoes, he has succeeded in producing some of the best grown and most healthy Cattleyas in the country, which during their season of flowering constitute an Orchid exhibition of unexcelled beauty.

ORCHIDS AT REGENT'S PARK.—The Orchids at the Royal Botanic Society's Exhibition last week included many specimens of more than ordinary merit, which could not be fully referred to in our report. The collection from Mr. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, was in every way deserving of the honour it received, for the plants were admirable examples of good culture, and represented some fine varieties. *Oncidium macranthum* magnificentum, which was certificated, is a handsome variety, with flowers of great size, the sepals beautifully margined with yellow, most

effective, and one of the best varieties that has yet been obtained. *Dendrobium Bensoniæ* was well shown by several competitors; but Mr. Salter's specimen, a fine bush-like plant about 2 feet in diameter, was especially handsome, and showed the beauty of this free-flowering and pretty species to the best advantage. *Cattleya Mossiæ* Southgatei, a magnificent variety, with large richly coloured flowers, was in first-rate condition, as also was *Dendrobium suavisimum*, 3 feet through, and loaded with golden spikes. Mr. Salter has repeatedly given good indications of his cultural skill, but on this occasion he surpassed his previous efforts. Prominent in Mr. Cobb's collection were *Lælia purpurata* with four fine spikes, and *Odontoglossum vexillarium* in vigorous health, bearing ten spikes of good-coloured flowers. Mr. Child, The Gardens, Garbrand Hall, had an extremely well-grown *Aerides Lobbi* with two panicles, one having four long branches, and the other with three, and one long unbranched spike. This was a particularly fine plant, and with *Cypripedium Stonei* major, which had eighteen large flowers, and *Aerides Fieldingi floribunda*, were the principal specimens in that class.

The nurserymen's Orchids were not quite up to the usual standard. Mr. James had several showy specimens, including *Cattleya Mossiæ* well flowered, *Odontoglossum Pescatorei* with an unusually large panicle of flowers, and the distinct *Odontoglossum caudatum aureum*. Mr. Cypher's most notable plant was *Brassavola Digbyana*, with several of its large white flowers and deeply fringed lips. Sir Trevor Lawrence's unique collection of *Masdevallias* attracted much attention, as it comprised several rare and interesting species, such as *M. bella*, *M. Backhouseana*, with about two dozen flowers; *M. platyglossa*, *M. Wagneri*, *M. tridactylites*, and *M. rosea*. *M. Harryana* was represented by several good varieties.

PRUNING DENDROBIUMS.—I have seen many communications upon this subject, but my experience is quite opposite to those who advocate the removal of the old pseudo-bulbs. In several cases which I have carefully tested, the growths resulting after the pruning have been much smaller than the preceding, and this has led me to the conclusion that some advantage is derived from the old stems. If this is not so why do they remain plump for so long after they become, as the pruning advocates maintain, useless?—W.

MAXILLARIA HARRISONI.—This old inhabitant of our gardens is not half so much grown as it deserves to be, for it is very rarely met with, especially in those establishments where Orchids form the chief feature. The flowers are indeed beautiful and highly fragrant, a recommendation alone which should command for it a place. It does well in a cool house all the year round, and under cool treatment flowers profusely at this season. It is, however, rather benefited than otherwise by being placed in an intermediate temperature while making its growth, as it is made quicker in heat than under cool treatment; and this is an advantage, because the pseudo-bulbs can be better and more completely ripened earlier in the season, thus allowing of a longer and more complete season of rest. This is important, for before the plant can be termed free-flowering it must enjoy a lengthened and complete rest, which will cause it to flower as freely as any Orchid. This *Maxillaria* is one of those plants which if kept in heat the whole year commences growth almost directly one set of pseudo-bulbs has been made, and when subject to this treatment the foliage soon presents a sickly appearance, and the plants seldom flower.

This is a very accommodating Orchid, and can be grown successfully in either a pot or a basket, the former being preferable. The *Odontoglossum* or cool house is not the best position to which to rest it, for the atmosphere is too moist. When growth is completed it will rest well in a vinery or any cool house where the atmosphere is moderately dry. While at rest no more water should be given at the roots than is really necessary to keep the pseudo-bulbs and foliage from shrivelling. While growing liberal supplies of water are beneficial. This plant grows well in peat fibre and lumps of charcoal, with the surface covered with living sphagnum moss.

ODONTOGLOSSUM VEXILLARIUM.—Judging this Orchid from a gardener's point of view it is perhaps the best of all *Odontoglossums*; the beautiful varieties of *O. Alexandræ* might perhaps be excepted. It would indeed be very difficult to name any Orchid more floriferous, for the smallest little plant will produce large flowers if allowed to do so. It is, however, a mistake to allow them to flower in too small a state, for the progress of the plants is much impeded by early flowering. Healthy specimens in 5 and 6-inch pots often produce during the spring and early summer months as many as four and five spikes each, bearing the same number of large flowers on each spike. A plant of this description well bloomed is in itself a picture, but a few dozen plants arranged amongst *Masdevallias* and other varieties of Orchids in a little house are delightful.

The demand now amongst enthusiasts is for dark forms of this lovely flower, and doubtless they are the most beautiful, but they are

the most costly; but for cutting or decoration of any description the light forms are equally good, and can be obtained for considerably less money. It is a very useful Orchid, because the flowers last for a long time in a cut state in water. The plants may also with safety be used for room-decoration when in flower, providing positions are selected for them where gas is not employed. They may also be used with advantage in the conservatory or any other structure kept gay with flowering plants, if shaded from strong sun and protected from cold draughts. When used in these structures they should not be crowded amongst other flowering plants, but be associated with *Adiantum cuneatum* or any other similar Fern, and the effect is all that can be desired. Those in search of useful flowering plants could not do better than obtain a number of small plants of this lovely Orchid.—B.

NAMING ORCHIDS.—It is very undesirable that the popular style of naming plants should be employed for Orchids, and I think that the Floral Committee ought to express some opinion upon this point when plants are exhibited with such names as *Souvenir de Prince Leopold*. If this practice is followed up we shall soon have as many "Souvenirs" as there are amongst the Roses. Again, there is much unnecessary multiplication of varietal names, and this is especially the case with *Masdevallias*. The smallest character is seized upon by the "namers," and a new variety is published, often misleading purchasers, who expect to find something really distinct, and perhaps have to search over the leafstalk to find a small protuberance, or carefully watch the flowers to perceive a delicate shade of colouring not previously observed. It is with these, as it was with a distinguished florist who had named a variety of *Narcissus*, and sent it to a friend, who was unable to distinguish it from one already known, and informed the sender of the fact. The reply was, That when the friend had had as many years' experience as the raiser he would have no difficulty in detecting the difference. It may be, however, reasonably suggested that if so much training is needed to appreciate small differences they are not worth naming, and the same applies to Orchids.—J. E. R.

SILVER CUPS FOR ORCHIDS.—It has been suggested to the Committee of the York Floral Fête that they should offer a silver cup for Orchids at their next exhibition, and other societies might also take the hint. We have cups for *Chrysanthemums* in abundance, and also for Roses, and why not for Orchids? It would undoubtedly add greatly to the interest of an exhibition, and would also induce a keener competition. A champion cup might be offered somewhat on the same lines as that at the Kingston *Chrysanthemum* Show, to become the property of the gentleman if won two or three times, a money prize to be given to the gardener.

MULCHING AND TOP-DRESSING.

At page 459 Mr. Iggulden contributes an extremely useful article on the advantages of top-dressing, and especially during such a season as the present. It is needful to give all the assistance possible. While I agree with Mr. Iggulden that almost any loose material may be employed with benefit, I have noticed that spent bark from the tanneries is not included in the list; whether it be from objection or that the writer has not considered it within reach generally, Mr. Iggulden, I feel sure, will not object to explain. My reason for asking this much of our practical friend is that very near to the gardens here spent bark is plentiful, can be obtained free of cost, and has for some years been freely used in various ways for mulching purposes for Strawberry crops, but most largely for shrubberies. The growth and colour of the foliage has greatly improved with its use, and also has a very neat appearance, is quite free from weeds, affords a very agreeable change, and in no case can we trace any injury from its use. Notwithstanding all this there are two sides to most cases, and I shall be glad to have Mr. Iggulden's opinion on the subject, or that of any other practical gardener who has tried it, which may be equally of benefit to others besides myself.—E. BURTON, *Kirkby Lonsdale*.

MELONS CANKERED—ALUM.

YOUR correspondent "G. S." may with confidence apply powdered alum to his Melons. Some one, two, or three years ago (I do not remember if it was Mr. Waiting) recommended powdered alum and flowers of sulphur in equal portions, to be applied to the affected parts. Since then I have used it, and found nothing better. But it is like everything else, it must be done in time, before the canker has too much hold of the stem. It is also an excellent plan to put a little of this on the cuts when thinning the young growths.—R. I.

ALEYRODES VAPORARIORUM.—I noticed a week or two ago a correspondent asking for a cure for the above-named insect pest. I give the following, which I have known to prove successful:—Fumigate the house with tobacco for two or three nights consecutively, and when the house is filled with smoke go round and shake the infested plants. This will

bring them out into the smoke, which will then have better effect upon them. It will also be found advantageous to have the floor well moistened.—JUSTITIA.

KING OF THE EARLIES STRAWBERRY.

A FORTNIGHT ago Mr. Gilbert of Burghley sent us the following note on this Strawberry:—

"LAXTON'S KING OF THE EARLIES STRAWBERRY.—I have a few fruits of this exquisite Pine-like flavoured Strawberry now (June 10th) ripe to-day. J. C. Hopwood, Esq., called in, and I asked him to taste it; he pronounced it excellent, also Mr. Hubbard, gardener, Holywell Hall, who described it thus: 'A very great novelty, ten days before any other, and much larger than Black Prince, with a Pine-like flavour quite its own.' With these remarks I fully agree."—R. GILBERT.

As was stated last year, when we gave a figure of The Captain Strawberry, King of the Earlies was raised from *Vicomtesse Hericart de Thury* × *Black Prince*, a prolific sort, which comes earlier than either of its parents, and quite as early as *May Queen*; but otherwise almost intermediate in character between those well-known and esteemed early market Strawberries. The fruit is of medium size, ovate even and angular; skin bright red on the shaded side, and dark mahogany on the side exposed to the sun; flesh white, with a tinge of red under the skin, solid, firm, and with a fine brisk and rich flavour.

Mr. Laxton has sent us a plant with fruits of this variety, which is represented in the woodcut (fig. 118), and it need scarcely be added after what is stated by Mr. Gilbert, that a Strawberry possessing such characters as extreme earliness combined with an excellent flavour is most valuable.

YORK FLORAL FETE.

JUNE 18TH, 19TH, AND 20TH.

THE twenty-sixth annual floral festival and gala was held on Wednesday Thursday, and Friday last week in the Bootham Fields, York, and in every respect well maintained the fame this northern Exhibition has gained in the horticultural world. Six huge tents radiated from a large central circular one—the same arrangement as that employed for several preceding years, and each one was an exhibition alone. The method of grouping exhibits of similar character together, such as the Ferns, Roses, *Pelargoniums*, fine-foliage plants, &c., does not admit of a very elaborate style of arrangement; but unless the ground were specially prepared this would be impossible, and in any case with so extensive a show it would be difficult to produce a general effect. As it is, the comparative merits of the exhibits are better seen, and the instructional value of the show is greater.

The progress of the York Exhibition has been gradual but steady, and the advance has been proportionate to the increase in the prize money. At one of the earliest shows the total amount of prizes was £150, this year it is £600, besides a considerable amount expended on other attractions, which raised the total outlay to something like £1000. This is a large investment, but with fairly favourable weather the Committee are assured of success, and this proved to be the case, for the numbers of visitors were even greater than usual. Exhibitors also were in strong force, and all the most important prizes were keenly competed for, the general quality of their productions being highly satisfactory.

The courteous and energetic Secretary, Mr. Wilson, deserves the greatest praise for his long and able service in connection with this Show. Since the establishment of the Show he has worked untiringly in its behalf, and there is no doubt that its success has been in a considerable degree due to his efforts, with the hearty and substantial support of an influential Committee.

PELARGONIUMS.

At nearly every show of importance throughout the kingdom there is one or more feature which is always of unusual merit, and which is maintained year after year as the great attraction of the exhibition. At Manchester the Orchids are *par excellence*, and in a similar degree the *Pelargoniums* at York are far in advance of all other shows. This year, however, some of the exhibitors have surpassed their previous efforts, and it is difficult to conceive in what way the magnificent specimens from Mr. Eastwood, gardener to Mrs. Tetley, Weetwood, Leeds, could be excelled. They were not, perhaps, so large as some that have been shown in other seasons, but in training, health, abundance and brilliance of blooms they were as nearly perfect as can be imagined. The large tent was filled to overflowing with the exhibits in the several classes, the central stage being devoted to the Show, Fancy, and Zonal varieties, which produced a display of colours that could only be excelled by Orchids. The side stages were occupied with the bronze and tricolor varieties, which have for many years received much attention in the neighbourhood, and are never seen so well grown and numerous elsewhere. The *Pelargonium* tent was indeed an exhibition in itself, of which any society might well be proud.

The leading class was for twelve Show varieties, Mr. Eastwood taking the first place with even handsome specimens, models of good culture and training, deserving the highest commendation. They were 4 to 5 feet in diameter, bearing numerous trusses of large finely formed flowers. The varieties were *Kingston Beauty*, *Conqueror*, *Duchess of Bedford*, *Madame Hillaire*, a very distinct variety with peculiar purple-tinted flowers; *Mary Hoyle*, *Duchess of Edinburgh*, *Triomphe de St. Mandé*, *Queen Bess*, and *Albina*. Mr. C. Rylance, Ormskirk, followed with creditable plants, but looser and smaller, though flowers were of wonderful size and substance.

Particularly fine were Queen Bess, Jewess, and Brigantine. Mr. MacIntosh, gardener to J. Hingston, Esq., Clifton, York, was third, but his plants were not sufficiently forward, many of the flowers being not expanded. Mr. Eastwood was again first with six Show varieties, equally as good as those in the preceding collection. The varieties were also similar, Queen Bess, Kingston Beauty, and Mary Boyle being the finest. Mr. MacIntosh was second with plants not quite at their best; and Mr. Vear, gardener to Miss Steward, The Laurels, Bishopsthorpe, York, was third. For three plants the prizes were awarded in a similar manner, Messrs. Tetley and MacIntosh gaining the first and second prizes, followed by Mr. H. Wright, gardener to G. Talbot, Esq.,

and also with six plants. They were, like the Show varieties, even symmetrical specimens, about 4 feet in diameter, and bearing some wonderfully large trusses of handsome blooms. Conspicuous amongst the varieties were Mrs. Kelley, Expedition, Masterpiece, The Shah, the Rev. Atkinson, Renown, Lucy, Lord Derby, Mrs. Lupton Santley, and Mrs. W. Paul. Very rarely are such grand plants seen at shows, or so well deserving of admiration. Messrs. Pybus followed with twelve, but though these specimens were large the varieties were too much of one colour to make so effective a display. Messrs. Bellerby and MacIntosh secured the remaining prizes in the same class, Mr. Hemsworth, Mr. Blakeley, and Mr. Bellerby obtaining similar

Fig. 118.—STRAWBERRY KING OF THE EARLIES.

Sonthfield, Leeds, and Mr. J. Blakeley, gardener to the Rev. H. Newton, Beechwood House, Driffield.

Following up his success in the Show variety classes Mr. Eastwood was first both with six and three Fancy varieties, charmingly neat and beautifully flowered specimens, amongst which Ann Page, Marginatum, Lucy, and Roi des Fantaisies were the most striking varieties. Mr. C. Rylance also had good collections of Fancy varieties, but the remaining prizes in the two classes were awarded for much smaller and weaker examples.

The Zonals were extremely gay, profusely flowered, and representing the most brilliant shades of scarlet, with fine shades of pink, and a few pure white. The singles were by far the most effective, and with these Mr. Eastwood was also the premier exhibitor, taking first honours with twelve,

positions in the class for six. The double varieties were not so pleasing although they are more useful for cutting, and retain their flowers longer than the singles. Mr. Eastwood secured the two premier prizes for six and three specimens, thus taking the leading honours in all the classes for flowering Pelargoniums. The most effective double varieties were Madame Thibaut, Dr. Jacoby, Clara Pfizer, and Jules Simon.

Many less ornamental-foliaged plants than Tricolor Pelargoniums are grown, and it is to be regretted that the latter have in recent years become somewhat neglected. A few are employed for bedding out, but large specimens, grown for the sake of their foliage alone, are rarely seen, though they are by no means to be despised. At York, however, exhibitors are liberally encouraged, and the result invariably is a good representative show. In the

class for six varieties Mr. Hemming, gardener to A. J. Cholmley, Esq., Newton Hall, Rillington, was awarded chief honours for richly coloured plants, flat-trained, about 3 feet in diameter, and well clothed with foliage. The varieties were William Sandy, Lass o' Gowrie, Mrs. Laing, Sophia Dumaresque, Prince of Wales, and Caroline Longfield—a selection of very distinct and effective varieties. Messrs. Pybus & Son and Mr. Lazenby, gardener to the Rev. G. E. Heworth, Vicarage, York, followed very closely; Mr. C. Rylance taking the fourth place. In the class for three plants Mr. Lazenby was the most successful exhibitor, showing extremely neat and brightly coloured examples of Flambean, Mrs. J. Clutton, and Lady Cullum—three effective and pretty varieties. He was followed by several of the exhibitors named in the preceding class, all of whom staged creditable and highly coloured specimens.

Bronze-leaved varieties were shown in great numbers and excellent condition. Mr. Stephenson, gardener to J. Bellerby, Esq., Burnholme, Heworth, York, secured the leading position with six varieties, staging specimen plants of Empress Eugénie, Black Dragon, Marshal MacMahon, Rev. Mr. Pearson, with others. Mr. Barnes, gardener to Mrs. Jackson, Pocklington, followed closely, Mr. MacIntosh being very good; and Mr. Clarke, gardener to Miss Wharton, Burton Grange, York, was fourth with neat plants. Mr. Stephenson was also first with three bronze varieties, showing Black Douglas, Earl Rosslyn, and Mrs. Harrison Weir, finely coloured; Mr. Barnes taking the second place with similar plants.

STOVE AND GREENHOUSE PLANTS.

Though somewhat late in the season for a large display of stove and greenhouse plants there is always some good representative collections, especially in the principal class for a group of ten flowering and six fine-foliage plants. The latter were on this occasion, as at previous exhibitions, arranged in the central circular tent from which all the other tents radiate, and the three entered formed a handsome group of large and well-grown specimens. Mr. Letts, gardener to the Earl of Zetland, Aske Hall, Richmond, Yorkshire, was the most successful exhibitor, and unquestionably merited the honour accorded him, for his plants were with one or two exceptions in magnificent condition. Very prominent was *Anthurium Schertzerianum*, bearing sixty or seventy large finely coloured spathes, and *Anthurium Andreanum* with nine spathes, each about 8 inches long by as much in diameter, both superbly grown plants; but the most meritorious specimen in the whole collection was a *Phenocoma prolifera*, 6 feet in diameter, of globular form, profusely flowered, and in perfect health; such a plant is indeed seldom seen. *Erica depressa*, 4 feet high and flowering very freely; *Aphelaxis maerantha purpurea*, very even and good; *Allamanda grandiflora*, about the same size; and a handsome globular *Ixora coccinea*, 5 feet high, and bearing a large number of full even trusses of flowers were the best of the other flowering plants, a one-sided *Azalea Duc de Nassau* being the greatest defect in the group. Of the foliage plants a gigantic *Croton Queen Victoria* with several Cycads were the most noteworthy specimens. Mr. J. Cypher, Cheltenham, was second with healthy but smaller and less effective specimens, among which the best were *Stephanotis floribunda*, a large *Pimelea diosmæfolia*, *Cordyline indivisa*, *Azalea Reine des Roses*, and *Kentia Fosteriana*. Mr. R. Berry, gardener to W. Dove, Esq., Crown Cottage, York, was awarded the third prize for neat little plants, and an extra prize was adjudged to Mr. Noble, gardener to T. Fry, Esq., M.P., Woodburn, Darlington.

In the class for six specimens Mr. Letts was again the premier exhibitor, showing beautiful examples of *Anthurium Schertzerianum*, 6 feet in diameter, *Ixora Williamsi*, *Erica Lindleyana*, and *E. ovata*. Mr. Noble followed, his two best plants being an extremely neat *Erica ventricosa coccinea minor* and *E. Cavendishiana*. Mr. C. Rollisson, gardener to W. Bateman, Esq., The Ridge, Harrogate, was third, having amongst other good plants an exceedingly fine *Statice profusa*, 3 feet across and grandly flowered. With three specimens Mr. J. Sunley, gardener to W. N. Champion, Esq., Upper Shibden Hall, Halifax, was first, showing *Imantophyllum miniatum superbum* with twelve large trusses, and *Anthurium Schertzerianum* in fine condition. Mr. H. Wright took the second place with a particularly handsome *Gloriosa superba*, 6 feet high, amongst others, and Mr. McIntyre was third, showing *Clerodendron Balfourianum* well flowered.

Heaths were small but healthy, and bearing numerous flowers, especially those from Mr. Cypher, which gained him the first place in the class for three. Messrs. Letts and Rollisson also exhibited neat specimens.

ORCHIDS.

In proportion to the extent of the Exhibition the display of Orchids at York is usually rather weak, and it would be a great improvement if a more spirited competition could be induced, as the time at which the Show is held is a very suitable one to procure a good number of effective Orchids, especially the magnificent *Cattleyas*. With this object in view it has been suggested that the Committee offer a valuable cup for ten or twelve specimens, which would probably bring some of the large growers, and create an interest in these classes that would well compensate for the outlay. It is to be hoped that the suggestion will be adopted, and with their present season's financial success to aid them there should be no difficulty in the matter. The largest class is that for six plants, in which Mr. J. Sunley gained first honours with *Cypripedium barbatum grandiflorum*, bearing thirty-six blooms; *Lælia purpurata alba*, with six flowers; *Dendrobium nobile*, well bloomed; *Odontoglossum vexillarium*, fine; *Anguloa Clowesi*, with twelve fine blooms; and *Cattleya Mossiæ*, the last-named being really three plants in a huge basket. Mr. C. Rollisson secured the second place, staging *Epidendrum vitellinum majus* in good condition; *Vanda suavis*, with three spikes; and *Saccolabium retusum*, bearing a spike 12 inches long. Mr. Cypher was third, his most noteworthy plant being a small *Cypripedium ciliolare*. For three Orchids Mr. Cartwright took the lead with *Cypripedium caudatum*, bearing eight large and unusually dark-coloured flowers; *Odontoglossum vexillarium* with ten spikes; and *Aerides Fieldingi*, very healthy. Mr. Sunley followed, showing *Dendrobium Devonianum*, with seven well-flowered pseudo-bulbs; *D. nobile*, healthy and good; and *Cattleya Mossiæ*. The third place was adjudged to Mr. Eastwood, who had *Aerides Fieldingi*, with three fine spikes; and the fourth to Mr. Rollisson for *Cypripedium caudatum* and *Dendrobium suavisissimum*, small but fresh. The best single specimen was *Trichopilia crispa*, with eleven flowers, from Mr. John Sunley; the second *Cypripedium superbiens*, with eight flowers, from

Mr. Jas. Sunley; the third *Cymbidium Lowianum*, with three spikes of thirteen flowers each, from Mr. Rollisson, a fine plant, which was described as having been in flower since February. The fourth was *Cypripedium barbatum superbiens*, well flowered, from Mr. Hemming.

ROSES.

A beautiful tent of Roses was provided, the blooms being abundant, bright, and generally of good substance. The plants throughout were healthy, with well-developed foliage, but in several cases were deficient in neatness of training. The grand Cheshunt giants, or the smaller but beautifully symmetrical Slough specimens, would have added greatly to the attractions of the Show, and would also have afforded good models for the other exhibitors. In the open classes the leading prizes were secured by Messrs. Pybus & Son, Monkton Moor, Ripon; Messrs. Jackson & Co., Cross Lane, Bedale; and Mr. H. May, Hope Nurseries, Bedale, who nearly equally shared the honours. The first-named exhibited some fine bushes of *Marquis de Gibot*, *Juno*, and *Edouard Morren*, while in another class Mr. May had *Madame Lacharme*, *Duchesse de Morny*, and *Eugène Verdier* in capital condition. The best single specimen of a dark variety was *Madame Lacharme*, 4 feet in diameter, with abundant large substantial blooms, from Messrs. Pybus & Son; and the best dark variety *Horace Vernet*, fresh and handsome, from Messrs. Jackson & Co. The principal amateur competitors were Mr. J. Vear, Mr. John Sunley, and Mr. Eastwood, but their productions though healthy were rather deficient in the blooms.

The cut Rose blooms were strongly represented, the competition being keen in all the classes. Mr. H. May was extremely successful, winning first honours with forty-eight, thirty-six, and twenty-four blooms, each collection well deserving its position. Some of the varieties especially well represented were *Marie Baumann*, *Paul Neyron*, *Madame V. Verdier*, and *Pierre Notting*. Messrs. Jackson & Co. and Mr. Eastwood were the other prize-takers in these classes. For twelve white and yellow Roses Mr. Finlay, gardener to Mrs. Maynard, East Layton Hall, Darlington, was first with a beautiful collection of blooms, *Gloire de Dijon*, *Marie Van Houtte*, *Safrano*, and *Devoniensis* being extremely fine. Mr. Swann, gardener to J. S. Eggington, Esq., Kirk Ella Hall; with Mr. Vear, Mr. Bonsall, gardener to G. B. C. Yarborough, Esq., Campsmount, Doncaster; Mr. Eastwood, and Mr. John Sunley, secured most of the remaining prizes.

FINE-FOLIAGE PLANTS.

Though not quite so extensive as other portions of the Exhibition, the classes for these plants included many specimens of great merit. Mr. Cypher's leading collection of six comprised a handsome *Dasylium acrotrichum*, *Kentia australis*, large and healthy; *K. Fosteriana*, similarly praiseworthy, and a beautiful example of the distinct *Bonaparte juncea*. Mr. Noble, who followed, had a fine *Dasylium acrotrichum*. The best three specimens were contributed by Mr. Letts, his premier plant being a grandly coloured *Croton Johannis*, 6 feet high and 8 feet in diameter, one of the most handsome examples of this variety we have ever seen; *Cordyline indivisa* and *Dasylium acrotrichum*, 4 feet high, were also good plants. Mr. McIntyre followed with *Cycas revoluta* and *circularis*, both admirable specimens; and *Croton Johannis*, fairly coloured. Mr. C. Rollisson's third-prize plants comprised *Beaucarnea glauca* and *Phormium tenax*, large and healthy. The premier single specimen was *Dasylium acrotrichum* from Mr. McIntyre, which was 5 feet high, in perfect health.

Crotons were not very numerous, but three good collections of four plants each were shown. Mr. Letts secured the first place with most praiseworthy specimens, strongly grown and superbly coloured. *C. Morti* was especially beautiful, 5 feet in diameter, with very large golden-veined leaves; *C. majesticus* was 7 feet high by 8 feet in diameter; *C. Johannis*, 6 feet across, was very handsome in colour; and *C. volutus*, of about the same size, was also a grand specimen. Mr. McIntyre's second-prize plants were large, but rather deficient in colour, *C. Disraeli* being the best. Mr. J. Russell, gardener to J. Buckle, Esq., Markgate, York, was third with less vigorous plants. *Dracaenas* were of moderate size and well clothed with foliage to the base. The best were shown by Mr. Noble and Mr. McIntyre. *Coleuses* were brightly coloured and evenly trained, Mr. W. Lazenby having the best six specimens, very neat and beautiful examples, flatly trained, and of good carefully selected varieties. Mr. A. Simpson, Heworth Moor, followed with rather looser specimens.

The prizes offered by Mr. B. S. Williams, Upper Holloway, London, for a collection of *Nepenthes*, brought one exhibitor, Mr. McIntyre, who was adjudged the first prize for small but well-grown plants of choice varieties.

FERNS.

Quite an agreeable contrast to the brilliant colours of the *Pelargoniums* was afforded by the numerous fresh green Ferns in the adjoining tent, and the idea of so placing these exhibits was an excellent one, which will doubtless become an established regulation. The principal class was for six exotic Ferns, in which Mr. Berry, who for many years has been a successful grower and exhibitor of such plants, was awarded first honours for extremely vigorous specimens, including a *Microlepia hirta cristata*, 5 feet high, with long handsome crested fronds drooping to the ground; *Davallia Mooreana* was similarly remarkable for its fresh healthy appearance, and *Nephrolepis davallioides furcans* showed the characters of that very distinct Fern to the best advantage. Mr. C. Noble gained the second prize with *Davallia Mooreana* in grand condition, fully 7 feet in diameter, bearing large clean beautiful fronds. *Adiantum concinnum latum* and *Gymnogramma sulphurea* were well represented. Messrs. Bailey & Son were third, their best plant being *Woodwardia radicans*, large and in excellent condition. With three Ferns Mr. Berry was again the premier exhibitor, and had another grand *Microlepia* equally as large as the other. Mr. Lazenby followed, having *Dicksonia antarctica*, *Adiantum tenerum* and *farleyense* neat and fresh. Mr. Noble secured the third place, *Davallia Mooreana* being his most effective plant.

Hardy Ferns were capitally shown, as is always expected at York, for there are many amateurs and others in the district who give especial attention to them. The best ten plants were from Mr. W. R. Robinson, who exhibited a most creditable collection, comprising a wonderfully fine specimen of *Hymenophyllum Wilsoni*, *Lastrea Filix-mas grandiceps*, handsome *Polypodium elegantissimum*, *Scolopendrium crispum latum*, and *Athy-*

rium F.f. plumosum, 6 feet high. Mr. C. Rylance took the next position with good Athyriums and Lastreas, Mr. Russell being third chiefly with Athyriums. Mr. Rodwell was the leading exhibitor with six hardy Ferns, healthy plants of distinct effective varieties. Mr. J. Russell had an excellent premier collection of thirty-six British Ferns, representing some of the best varieties in cultivation.

Selaginellas were beautifully shown by Mr. Blakeley, who had much finer, more accurately named specimens than are usually seen at exhibitions. Martensi, Kraussiana variegata formosa, Poulteri, and aurea were the best varieties. Mr. Russell was second with Uncinata viticulosa and Wildenevii especially good, Mr. Berry being third.

GROUPS.

Two classes were devoted to groups of plants arranged for effect in a space of 250 and 150 square feet respectively, and the seven groups entered filled a large tent, which was certainly not the least pleasing portion of the Show. Mr. McIntyre won chief honours for the larger group, which was distinguished by its free graceful style of arrangement. The centre and body were chiefly Kentias, Cocos, Crotons, Acalyphas, and Adiantum gracilimum, with a neat margin of Panicum variegatum, Ericas, Hydrangeas, and small Ferns, with a few Oncidium spikes showing amongst the foliage. This group was an extremely pretty one, but a little more colour would have improved it. Mr. R. Simpson, Selby, was second with a good group, rather brighter than the first, but not quite so graceful. Mr. Berry was third with an effective group, perhaps a little too much of the orthodox pattern to please the Judges, and Messrs. Bailey & Son were fourth with a rather heavy arrangement. In the smaller group class the first prize was also awarded for one in which foliage plants predominated, but it was far from dull. This was arranged by Mr. Noble, every plant being well placed, the general smoothness without formality being very satisfactory. Mr. Russell was second with a slightly crowded but otherwise pretty group; Mr. R. Baker being third for a neat but too formal group, a style which is now discouraged by most judges, though it still finds favour with a few.

MISCELLANEOUS CLASSES.

Of the smaller classes not mentioned in the previous notes that for a collection of twenty alpine herbaceous plants was an interesting and well-filled one. Messrs. Bailey & Son were the most successful exhibitors, taking the first place with showy plants of Spiraea Aruncus, single and double Pyrethrums, Hemerocallis flava, Delphiniums, and others of similar character, effective useful plants, but none very choice or rare. The second position was accorded to Messrs. W. H. & J. H. Rodwell for plants resembling the others, but scarcely so vigorous or well flowered. Mr. R. Simpson was third, his best plants being some excellent Pyrethrums. Gloxinias were admirably shown, the plants in all the collections being strong, with good foliage and abundant large, well formed, and richly coloured flowers, Messrs. Russell, Sunley, Berry, Dawe, and Blakeley being the prizetakers. Calceolarias were distinguished by rather small flowers, and rather too thin, tall growth, though the colours were good. Bedding plants as usual made a good display, Messrs. T. Simpson & Son being the principal exhibitors with a good collection.

CUT FLOWERS.

A considerable space of the staging in the fruit tent was occupied with numerous exhibits in the cut-flower classes, and a keener competition or better quality flowers we have not seen at any show this year. For twelve bunches of flowers Mr. McIndoe won the leading prize with beautiful examples of Phalenopsis grandiflora, Odontoglossum vexillarium, Erica insignis, Callistemon rigidus, and Odontoglossum Roezii. Mr. Cartwright took the second place for a collection but little inferior to the preceding, beautiful examples of Phoenocoma prolifera, Aerides, Statice, Allamandas, Ixoras, and Ericas. Messrs. Letts and Black followed with good stands. Again, with six bunches, Mr. McIndoe led the way, followed closely by Messrs. Cartwright and Noble. Eight competitors entered the class for twelve bunches of hardy herbaceous perennials, Mr. McIndoe continuing his success by securing the first prize with a fine collection, including Inula grandiflora, Thalictrum aquilegifolium, double white Rocket, Pæonies, Pyrethrums, Lilium candidum, Delphinium nudicaule, and Delphinium Belladonna. Mr. G. Holmes secured the second award with Campanula dahurica, Gladiolus communis, and Geum coccineum, very fine. Mr. Short, gardener to A. Pearse, Esq., Hummersknott, Darlington; Mr. Hutchinsen, and Mr. Kirlew were all awarded prizes for good flowers. Messrs. Laird and Son, 17, South Frederick Street, Edinburgh, offered prizes for trays of twenty-four bunches of Pansies and twelve bunches of Violas. Mr. J. G. Craig was successful in the Pansy class with fine symmetrical blooms; and Messrs. Harkness & Son, Bedale, secured that award in the Viola class, extra prizes being adjudged to several exhibitors.

Bouquets were well shown, Mr. Cypher, Mr. Wright, Mr. C. Rylance, and Mr. Webster being the prizetakers for pretty combinations of Orchids and miscellaneous stove flowers. Stands of flowers were exhibited by Messrs. Lunt, R. Dickenson, and Wright, who were awarded the prize in that order for tasteful arrangements.

FRUIT.

Seventeen classes were devoted to fruits, open to all exhibitors, the prizes being extremely liberal, ranging from £8 to 10s., and, as usual, the competition was keen. The date of this Show is, however, too early for fruit to be shown in its best condition, especially by northern growers, and in consequence there was in some cases an evident deficiency in colour. On the other hand, however, there were also several exhibits of more than ordinary merit, and indicating the most satisfactory culture, some of the black Grapes and Melons deserving especial praise.

Collections.—The premier class in the fruit department of the Show is invariably that for eight distinct varieties, and on this occasion there were three competitors, each staging good produce, but perhaps not quite up to the standard of some previous shows at York. Mr. J. McIndoe, gardener to Sir Joseph Pease, Bart., M.P., Hutton Hall, Guisborough, was first with Black Hamburg Grapes, even, well coloured, and large in berry; Muscat of Alexandria, rather green; a fine Queen Pine; Best of All Melon, finely ripened; Royal George Peaches of medium size but rich colour; Pitmaston Orange Nectarines well ripened; Figs fair, and Alexandra Noblesse large.

Mr. Westcott, gardener to the Duke of Cleveland, Raby Castle, Darlington, was second, his Foster's Seedling Grapes, Best of All Melon, and Lord Napier Nectarines being the best dishes. Mr. N. Black, gardener to the Misses Pease, Southend, Darlington, was third, Dr. Hogg Peaches and Buckland Sweetwater Grapes being very good. For six varieties Mr. McIndoe was again first, a grand fruit beautifully netted of Melon Best of All being the most notable in the collection; his Black Hamburg Grapes were well coloured and large. Mr. Wallis, gardener to Sir H. M. Thompson, Bart., Kirby Hall, York, was second, showing large Black Hamburg Grapes, but very much rubbed and wanting in bloom; Grosse Mignonne Peaches in the same collection were of great size. Mr. D. Melville, gardener to Mrs. Hornsby, St. Vincent's, Grantham, was third with rather small samples. For four varieties Mr. Clayton, gardener to J. Fielden, Esq., Grimston Park, Tadcaster, won the chief position, having Violette Hâtive Nectarines and A Bec Peaches in praiseworthy condition. Mr. G. Cartwright, gardener to H. Wilson, Esq., Tranby Croft, Hull, followed with good Peaches, but rather rough Black Grapes. Mr. McIntyre, gardener to Mrs. G. Pease, Woodside, Darlington, taking the third place.

Pine Apples.—Only three Pine Apples were staged, all Queens. Mr. T. Hare, gardener to R. H. O. Neville, Esq., Grantham, leading with a well-developed and ripe fruit, followed by Mr. Black and Mr. Craig, gardener to J. Hutchinson, Esq., Eggleston Hall, Darlington, with much smaller fruits.

Grapes.—The entries were moderate in these classes. Five good lots of three bunches of Black Hamburgs were entered. Mr. James Johnson, gardener to Hugh Gill, Esq., Boston Spa, secured chief honours with even bunches of moderate size, but bearing a fine dense bloom. Mr. Alsop, gardener to Lord Hotham, South Dalton Park, Driffield, was second with a less even collection; two were, however, finely ripened. The third position was accorded to Mr. Dawes, gardener to the Hon. Mrs. Ingram, Temple Newsam, Leeds, for samples of good colour but small in berry.

White Grapes were with few exceptions much too green. Mr. J. Jefferson, gardener to F. Earnshaw, Esq., Sheffield, was first in the Muscat of Alexandria class, staging three of the best ripened bunches that have been yet exhibited this season; the second prize going to Mr. McIndoe for Muscat of Alexandria, very irregular and imperfectly ripened. Mr. Clayton was third with Muscats far too green to be cut, and certainly not fit for exhibition, though large in bunch and berry. In the Any other white variety class Mr. Dawes won premier honours with Foster's Seedling, well-ripened and good bunches. A. Wilson, Esq., followed with Buckland Sweetwater small but ripe, and Mr. Alsop was third with Foster's very green.

Peaches.—Ten dishes of creditable Peaches were entered, Mr. Puzey, gardener to W. H. St. Quintin, Esq., being first with Crimson Galande large and deeply coloured; some of the finest examples we have seen. Mr. Mitchell, gardener to Lord Wenlock, York, was second with Violette Hâtive large and handsome; A. Wilson, Esq., being third with the same variety in nearly equally as good condition.

Nectarines.—Eight dishes of Nectarines were staged, but these were not so meritorious as the Peaches, being mostly small and rather unripe. B. Hansworth, Esq., Mr. McIndoe, and A. Wilson, Esq., were the prizetakers.

Melons.—There were six competitors in the class for one scarlet-flesh Melon, Mr. McIndoe leading with Scarlet Premier large and superbly netted. Mr. J. Edmonds followed with the same variety in greatly inferior condition, and the Misses Pease were third. Mr. Dawes had the best green-flesh Melon—viz., Victory of Bath, small but thoroughly ripe. Mr. Mitchell followed with a small, peculiar, deep green Melon known as Dickson's Exquisite, and Mr. A. Wilson was third with the same variety. In the white-flesh Melon class Mr. Melville, Mr. J. Edmonds, and Mr. Mitchell were the prizetakers with good plants of unnamed varieties. Figs, Cherries, and Strawberries were not largely shown.

Cucumbers.—The competition was extremely keen in the class for a brace of Cucumbers, no less than twenty being staged, all very close in merit. Mr. McIndoe gained the first prize for Verdant Green, two neat straight fruits. Mr. Daglish, Aldborough, was second with fresh young fruits of a favourite variety of his own. Mr. C. Rylance was third with Telegraph, two good fruits.

Tomatoes.—A pretty display of Tomatoes was formed by the eight entries in a class for a dish of twelve fruits. Mr. McIndoe was first with Hackwood Park Prolific, very brightly coloured. Mr. Jefferson was second with Dedham Favourite, round, even, and beautiful in colour. Mr. Fielden followed with Hackwood Park, neat and good colour. In the opinion of many persons the second lot was preferable to the first in this class, as the Hackwood Park variety was rather too much corrugated.

VEGETABLES.

Five clean good collections of vegetables were entered, the premier position being secured by Mr. J. Hemming, gardener to H. J. Cholmley, Esq., Rillington, for a most praiseworthy contribution, including Snowball Cauliflowers, Sutton's Improved Telegraph Cucumbers, Filbert Kidney Potatoes, Canadian Wonder Beans, Hathaway's Excelsior Tomatoes, very good; The Baron Pea, Carrots, and Asparagus. Mr. McIndoe was placed second with a more tastefully arranged collection on Parsley, but there was no Asparagus or Beans, though The Paragon Peas, Onions, Carrots, Cucumbers, and Potatoes were good. Mr. H. Wilson was third with a neat collection. Mr. R. Kirk, Acomb, York, showed a fine basket of vegetables not for competition, including some particularly good Asparagus, Mushrooms, and Tomatoes.

Not-for-competition exhibits were shown in moderate numbers, but Mr. B. S. Williams, Upper Holloway, London, contributed a beautiful collection of choice Orchids and other stove plants, including many novelties of the present season's introduction. Messrs. Richard Smith & Co., Worcester, had a handsome group of Clematises of selected good varieties. Messrs. Bailey and Son showed an extensive collection of Tuberous Begonias; and Messrs. Harkness & Sons exhibited a large number of beautiful Pansy blooms.

With the exception of a little rain on Thursday evening the weather was favourable on each of the three days, and on the second the number of visitors was very large, the town being crowded with excursionists.

THE EUCALYPTUS IN IRELAND.—Writing to the *Irish Farmers' Gazette* upon this subject, Mr. C. Roberts, Mayfair, observes as

follows:—"I think the subject of the acclimatisation of the tree cannot be determined by the history of a few solitary specimens. The young trees should be planted in considerable numbers close—very close together—so as to shelter each other from the wind and cold. Some will die, but others will survive, just as they do in warmer countries like Spain and Portugal. I was in Spain this last winter and saw a considerable number of Eucalyptus trees killed by a severe frost, which I think occurred in November. Many of the trees, however, survived, and indeed the leaves did not show the slightest injury from the cold, and dead and living trees were seen standing side by side. Exactly the same thing occurred in some of the Olive plantations near Granada and Cordova. The frost had killed some, while others in exactly the same situations were little affected by it. Some Orange trees at Seville were in the same condition. It is obvious that trees of the same species have different constitutions, and it is only by experimenting that the hardy ones can be selected. The great mistake which has been committed in this country has been the planting of the Eucalyptus in too rich or too damp soils, by which mistake the tree grows too freely, and does not ripen its wood for the winter. The soil cannot be too poor or dry, especially for the young tree. It is a great error to think that the tree grows in swamps in its native country of Tasmania. Some of the finest trees I have seen grew on the bare rocky slopes of the mountains about Hobartown, and when I saw them a few years ago they were covered with snow. The nature of the roots is that they shall be able to absorb moisture where only little is to be found, and not to live in damp places."

ROYAL METEOROLOGICAL SOCIETY.

THE concluding monthly meeting of this Society for the present session was held on Wednesday evening, the 18th inst., at the Institution of Civil Engineers, Mr. R. H. Scott, F.R.S., President, in the chair. Dr. Benjamin A. Gould, Director of the Cordova Observatory, Argentine Republic, was elected an honorary member.

The following papers were read:—

1, "The Equinoctial Gales—Do they Occur in the British Isles?" By Mr. R. H. Scott, F.R.S. The period investigated was the fourteen years 1870—84, and only those storms were selected which had attained force 9 of the Beaufort scale at more than two stations. The results show that the storms are all but exclusively confined to the winter half-year; and also how, for a certain interval, the stream of storm depressions set over the British Isles, and then for a time takes another path, leaving this country at rest. In some years there are as many as four or five storms in a fortnight, and in others there are none or only one. It is further shown that there is no strongly marked maximum at either equinox.

2, On the Physical Significance of Concave and Convex Barographic or Thermographic Traces," by the Hon. R. Abercromby, F.R.Met.Soc. The author shows that a falling barogram is convex when the rate of the fall is increasing, concave when decreasing; and conversely, that a rising barogram is convex when the rate is decreasing, concave when increasing. As the rate of barometric change is proportional to the steepness of the gradients which are passing, and the wind also depends on the gradients, the author suggests the following rules for judging the coming force of a gale from the inspection of a barogram. A convex barogram is always bad with a falling thermometer, and good with a rising one, and a concave trace is sometimes a good sign with a falling barometer, and not always a bad indication with a rising one. The convexity or concavity of a thermogram is likewise shown to depend on the rate of thermal change. A method is given by which the distribution of diurnal isotherms over the globe can be deduced from the diurnal thermograms in different latitudes; and it is shown that the shape of diurnal isotherms on a Mercator chart, for a limited number of degrees of latitude, is similar to the shape of the curve of diurnal temperature range, if we turn time into longitude and temperature into latitude on a suitable scale.

3, "Maritime Losses and Casualties for 1883 Considered in Connection with the Weather," by Mr. C. Harding, F.R.Met.Soc.

4, "The Helm Wind," by the Rev. J. Brunskill, F.R.Met.Soc. This is an account of a wind peculiar to the Crossfell range; and its presence is indicated by a belt of clouds, denominated the "helm barr," which settles like a helmet over the top of the mountain.

5, Climate of the Delta of Egypt in 1798 to 1802 during the French and British Campaigns," by Surgeon-Major W. T. Black, F.R.Met.Soc. The author has collected and discussed the meteorological observations made in Egypt during the French and British campaigns at the beginning of the present century.

EXHIBITING ROSES.

SINCE I commenced taking your valuable Journal, nearly two years ago, I have derived much practical information from the columns of it, especially regarding that universal favourite the Rose. About a year ago I asked you for some information with regard to the budding of Roses, and you were kind enough at that time to publish a first-class article on the subject, accompanied by woodcuts. Pardon my again troubling you for some other information. As the exhibition season is once more at hand I would be glad if you could give me some hints as to the staging of Roses for exhibition. What is the proper method of doing so? Here in Scotland the usual way is to add a lot of foliage to the blooms, which are set into zinc tubes resting on the boxes; consequently the blooms are lying flat on the board. I understand there is a much better method of staging than this, and that is to cover the boxes with nice moss, to support the blooms with wire clips, and with nothing but the foliage as cut from the tree. I have great difficulty in getting nice moss. Is there any way of dyeing this to make it greener? How are wire clips made, or where can they be had?

Any information you can give me through the columns of your valuable paper will be acceptable by—AYRSHIRE AMATEUR.

[From Canon Hole's far-famed "Book About Roses" (Blackwood and Sons) we cite the following, that will be useful to many on the eve of the Rose season.

"At our first National Rose Show we commenced a reform in showing Roses by an act of uniformity as to size and shape of boxes. The amateur must therefore order his boxes, which any carpenter can make for him from three-quarter-inch deal, to be of the following dimensions:—

	Length.	Breadth.	Height.
For 24 Roses,	3 feet 9 inches.	1 foot 6 inches.	Back of box 7 inches, front 5.
" 18 "	2 " 9 "	" "	" "
" 12 "	2 " "	" "	" "
" 6 "	1 foot 3 inches.	" "	" "

The covers, being 8 inches in depth at the back and 6 inches in front, being $1\frac{1}{2}$ inch longer and wider than the boxes, and having a narrow beading within the four sides, half an inch from the bottom of the lid, overlap the boxes, leaving ample room for the Roses, and are secured for travelling by stout leather straps. Within the boxes some exhibitors have holes pierced at equal distances on a uniform surface of wood; but as Roses differ in size, it is more convenient to have the facility of placing them where we please, and for this purpose it is desirable to have strong laths (three-fourths of an inch in depth and $1\frac{1}{4}$ inch in width) extending the length of the box. These laths should be six in number, and should be nailed on two strong pieces of wood, crossing the box one at each end, 2 inches below the surface. The upper and lower laths should be fixed one-eighth of an inch within the box, and the four remaining so arranged that there will be six interstices $1\frac{1}{4}$ inch in width—three for the Roses and three merely to reduce the weight. There will be a space of $1\frac{1}{4}$ inch between the laths and the upper edge of the box to be filled as follows:—Cover the laths with sheets of brown paper, two deep and cut to fit the box, and upon these place the best moss you can obtain. I get mine from trunks of trees in a neighbouring wood, have it carefully picked over and well watered the day before a show, and then, using the coarser portion for a substratum, make my upper surface as clean and green and level as I can.

Fig. 119.

Fronds of Ferns, especially of *Adiantum*, are sometimes prettily introduced.

"It would, I think, repay the rosarian to grow moss specially for this purpose such as would thrive—*Selaginella denticulata*, for example—in rough boxes and waste places under stages or in vineries. Some years ago I placed a lining of zinc 3 inches deep at the top of one of my Rose boxes, filled it with earth, and soon obtained from it a charming surface of *S. apoda*.

"The Roses are placed in tubes of zinc $4\frac{1}{2}$ inches in length, 2 inches wide at the top, gradually tapering until they become 1 inch in width at the centre, the tops being moveable, as shown in fig. 120. This top is taken off, and the stalk of the flower being brought through until the Rose is held securely, it is replaced upon the tubes, previously filled with pure rain water. These tubes not only facilitate the arrangement of the flower, but they retain the water when rough railway porters forget their gradients. They may be had from the brazier and tinman everywhere, and the cost is 4s. per dozen.

"The young knight will not be armed *cap-à-pie* until he has supplied himself with a couple of helmets. If the weather is showery or the sun scorches just before a show, many Roses may be advantageously shaded by having a zinc cap placed over them 8 inches in diameter, 5 inches in depth, ventilated, and having a socket attached, which may be moved up and down a stake fixed by the Rose tree until the cap is secured in its position by a wooden wedge inserted between the socket and the stake (fig. 121). Roses of a more delicate complexion than others—such as Madame Lacharme and Monsieur Noman—and some whose vivid colouring is quickly tarnished by fiery suns—such as the brilliant Baronne Bonstetten, Louis Van Houtte, Reynolds Hole, and Xavier Olibo—may be thus preserved for exhibition. Fresh Cabbage leaves, renewed from time to time, may be advantageously placed on the caps, which, I may add, have a more pleasing appearance in the rosarium when painted a dark green colour.

"These caps should be in readiness, fixed upon their stakes in the Rose beds or near them, so that they may be quickly placed in position when there is peril from fire or water—when fierce suns come suddenly forth, or when those first large drops, which have been poetically termed 'tears of the tempest weeping for the havoc to follow,' give warning of

the storm. Many a grand Rose have I saved by promptly acting upon this admonition, and have come indoors with my heart rejoicing under its moist merino waistcoat.

"Helmet No. 2 resembles No. 1, except that the top is made of glass and is flat. This is used to accelerate the opening of Roses, and sometimes with success; but generally I have found that nature will not be hurried, and the Rose has been more refractory than the heat.

"In using these caps—and their use, be it remembered, is exceptional—the amateur must be on his guard against placing them too near the Rose, lest, when moved by the wind, the petals should be injured by trituration. And not only in this instance, but in all, he must so watch his trees as to prevent all risk of that contact and chafing which quickly ruins the Rose. Watching the flower as it sways to and fro in the summer breeze, he must remove all leaves and shoots which, touching it, would mar its beauty.

"I strongly advise the amateur who has no such wealth of material, and must make the most of his limited means, to cut his Roses whenever he has the option—that is, the time—upon the morning of the show. If

Fig. 120.

Fig. 121.

the weather is broken, and clouds without and barometer within warn you of impending rain, then gather ye Roses while ye may, in the afternoon and the evening before the show; but if it is

In the prime of summer-time,
An evening calm and cool,

let your Roses rest after the heat of the day, and cut them on the morrow, when they awake with the sun refreshed with gracious dews."

Those who desire more particulars on growing and showing Roses will find them in the "Book."]

SCOTTISH PANSY SOCIETY.

As certainly as the third Friday in June comes round, so surely do we find the Pansy holding high court in the beautiful metropolitan city of Scotland. For the past forty years the florists have worshipped the flower of their choice, and, if we may judge from appearances at the past Show on Friday last, that flower has never had so many patient wooers for her favour. We may occasionally be amused at the peculiarities of ardent florists, but to them we are indebted, and solely indebted, for one of the most beautiful of hardy flowers, and flowers, moreover, that are within the reach of everybody who has a few yards of garden ground. To the uninitiated in the nice points of judging the Show and Fancy varieties there would appear to be slight improvement on these during the past few years; but there is an improvement nevertheless. However, in the case of the Violas the most startling improvements are apparent. In ordinary garden decoration these newer forms, "fancy" in their colouring, have a great future before them, and gardeners wishful of keeping abreast of the times should secure a selection of the best novelties—not for bedding, but for dotting about on borders, and above all for filling small glasses. The one feature of the Show that was displeasing was the exhibits in the classes devoted to ladies for decorating epergnes, baskets, glasses, &c. Pansies and Violas were the only flowers allowed, and well these are fitted for the purpose, but in no case did we find a single shoot or leaf of a Pansy employed as a setting. There was Maiden-hair in superabundance, common Ferns, Myrsiphyllum, Myrtle, and many other kinds of foliage, but there was not one naturally arranged.

The prize list is such a long one, and the number of competitors so large, that we cannot do more than note some of the more generally interesting classes. Of these the few devoted to nurserymen are most noteworthy on account of the excellence of the blooms staged, and also because the best varieties were therein found. For eighteen Show sorts Mr. Sutherland, Lenzie, took the premier position with clean, even, and beautiful blooms. The names of these were James Edgar, D. L. Whitton, David Malcolm, Archie Ormiston, Peter Lyle, dark selfs; Mrs. Dobbie and Mrs. Turnbull, white selfs; Gomar and Geo. McMillan, yellow selfs, the latter also taking the prize for the best yellow self; Jessie Foote (the best white ground), Mrs. J. Millar, Mrs. D. Wallace, N. D. Pownall, and Mrs. Ewart, white grounds; David Dalgleish, William Dickson, Sir W. Collins, and Dr. D. P. Stewart, yellow grounds; Miss Bowie, a primrose self, and an unnamed seedling. Messrs. Paul & Son, Paisley were second, and Messrs. Ormiston & Co., Anstruth, third. In the latter stand to Archie Ormiston was awarded the prize for the best dark self, and in Messrs. Dickson & Co.'s stand J. Balfour Melville was chosen as the best Pansy in the Show.

In the corresponding class of eighteen Fancy varieties Messrs. R. B. Laird & Sons, Edinburgh, were placed first with a stand of beautiful blooms. The sorts were Evelyn Bruce, Miss Bliss, Hecla, Countess of Home, May

Tate, James Gardiner, Mrs. Scott Plummer, William Dean, Mrs. J. W. Bennet, William Wondle, Mrs. McComb (extra fine), Peter Nicol, Mrs. Jameson, Mrs. Forrester, William Bennet, Perfection, J. Murray, Prince Silverwing, Mrs. J. D. Donald, Catherine Agnes, and seedlings. For these Messrs. Dickson & Co. were second, and the same firm were first for six seedling Show Pansies—Paragon, a clear yellow self; Archibald Roland, very dark yellow self; William Frater, very dark plum self; and Dr. Hector Wilson, a white self, being the best varieties. For twenty-four bedding Violas Messrs. R. B. Laird & Sons were first; the most striking varieties were Columbine, Duchess of Albany, Mrs. Cobham, Skylark, Queen of Crimsons, William Palmer, Mrs. J. Cowan, Countess of Kintore, Mrs. Peebles, and Owen Cameron. In Messrs. Dickson & Co.'s second-prize stand the most noteworthy were Merchiston Castle (very beautiful), The Meams, and Break of Day.

The chief competitions in the gardeners' classes were those for eighteen Show Pansies, Mr. Borrowman, Beeslack, taking the first place; Mr. R. Stewart, Lenzie, the second; and Mr. R. Miller, Paisley, the third. Mr. Cuthbertson, Corstorphine, was first for twelve blooms, and Mr. Borrowman second, the same exhibitors occupying the same positions for six blooms. In the Fancy classes for eighteen blooms Mr. Borrowman again took premier position with a stand of fine blooms, Mr. Stewart running a close second. Mr. Robert Smith, Aberdeen, showed twelve fine blooms for the first place for these, Mr. Borrowman being a good second; and for six blooms Mr. Cuthbertson had first, and Mr. McComb, Montrose, second.

In the amateurs' classes, and for eighteen Show sorts, Mr. Ritchie, Denny, was first; Mr. L. T. Fleming, Berwick-on-Tweed, second; and Mr. James Skinner, Penicuik, third. For twelve the first prize went to Mr. Stewart, Campsie; the second to Mr. Ritchie, who also had first for six, Mr. Thomson, Penicuik, being second. Mr. Storrie, Lenzie, was awarded first for eighteen Fancy sorts, and Mr. Stewart second; and for twelve blooms Mr. Galloway had first and M. L. T. Fleming second; Mr. Black, East Calder, being first for six blooms.

In the classes open to gardeners and amateurs the latter carried off all the prizes, Mr. Galloway being first for six Show and six Fancies; for eighteen Fancies Mr. Storrie; and for twelve Show and twelve Fancies Mr. L. T. Fleming. For four Pansies in pots Mr. Black was awarded the prize, the plants being strong and well bloomed. In addition to those already noted in the best single-bloom classes Mr. Ritchie showed a seedling for the best yellow ground; Mr. Stewart the best white self with Mrs. Dobbie; Mr. McComb the best mauve; and Mr. Ross the best crimson self respectively. The other prize blooms could not be found—indeed the whole arrangements from a reporter's point of view were far from satisfactory.

First-class certificates were granted to the following, all Fancies:—To Mrs. P. Lutz from Messrs. Dobbie & Co., Rothesay; to Mrs. Greive from Mr. Black, East Calder; to Mrs. Ferguson from Mr. Borrowman, Beeslack; and to Mrs. Gladstone from Messrs. Paul & Sons, Paisley.

The following are the classes devoted to ladies:—"A table glass arranged with bedding Violas," for which Miss Owen, Knockmillar, was first and Mrs. Laird second. "Most tastefully arranged small glasses of bedding Violas," first Mrs. D. P. Laird, second Miss Greive. "Basket bedding Violas," first Miss Balfour, second Miss Effie Welsh. "For the most novel and tasteful design in Pansies and Violas," first Mrs. D. P. Laird, equal second Miss Balfour and Miss Owen.

AURICULAS IN IRELAND.

My acquaintance with these dates back just about half a century. Those were the days when Dr. Plant reigned supreme, occupying in Ireland much the same position as Mr. Horner does in this country, but they were days before many of our best varieties were invented. There were no George Lightbodies or Lancashire Heroes, no Smiling Beauty or Acmes, no Pizarros or Heroines; but they were none the less days when the Auricula was understood and well cultivated, when varieties which we rarely see were grown in great perfection, unless indeed youthful reminiscences are, as they often are, coloured largely with rosy tints. Have I not seen in the doctor's collection row after row of Booth's Freedom and Page's Champion? And then what Colonel Taylors he used to exhibit! what grand Glories! and unless my recollection betrays me, Hey's Apollo was a beat on many of the blue selfs we now have. But those days are long past, and many of the flowers then exhibited would not be tolerated now. Then, again, some twenty years ago I knew how well Auriculas were grown, how excellent Mr. Tandy used to grow and show his plants, how select was his collection; here, indeed, all the crack varieties were to be found in quantities, and Lightbodies and Heroes which would delight the most critical northern taste were in abundance, for he had no sympathy with the coarse overgrown flowers which too often find favour with the southerners in England, and his success at the spring shows of the Royal Horticultural Society of Ireland bore witness to the excellence of his culture; but removal led him to abandon their culture, although his love for them has no way diminished.

In my recent visit I was informed that the same decadence in the culture of florists' flowers which we have lamented in the south of England has prevailed in and about the Irish metropolis. I heard of one or two growers besides those I visited, but as a fact Auriculas do not hold the position there they once did. The two collections I did see were those of my excellent friend and thorough florist, the Rev. F. Tymons of Baden Hill and Mr. Edward Kavanagh, nurseryman, of Ballybrack, and a few notes on these may not be unacceptable to the lovers of the flower.

Mr. Tymons' garden, a delightful old-fashioned one full to overflowing of grand herbaceous and alpine plants, is situated near Portmarnock, on the north side of the city, a place dear to the entomologist, and where in my early days I made many an excursion in quest of Lepidoptera and their larvæ; and there is a delightful view of Howth and Ireland's Eye from the front of his snug little bungalow. His collection of Auriculas is not large, but then it is very select. By degrees he has rooted out all the inferior varieties, and is confining himself to the really standard

sorts. These I need hardly enumerate, but he spoke highly of Mr. Douglas (Simonite) as a fine self, and of Acme as a really grand white. In greys he has seen nothing yet to surpass those well-known favourites George Lightbody and Lancashire Hero. He has Conservative, Mr. Douglas's fine new flower, and others of grand repute which are not in the lists. His Richard Headleys are well known, and are of a very superior character, as the plants he sent to Manchester last year will bear witness. Never probably was such a plant of that very chaste and refined flower shown. I need not say that his plants, though not overgrown, were in good condition. He grows them for themselves, as he has given up exhibiting them.

Mr. Kavanagh's collection is one of the most extensive I have seen of late years. He lives at Ballybraek, a charming village on the Wicklow side of Killarney; and he is one of those who grow Auriculas not so much as a source of profit as because he loves the flower. Frame after frame was filled with large and well-grown plants of most of the leading kinds in luxurious health, and evidently delighting in the care with which they were treated. Large quantities of Robert Traill, Mrs. Sturrock, George Lightbody, and most of the good sorts were there, while such kinds as Prince of Greens, F. Simonite, and others of the same varieties were of course in smaller quantities; but judging from the pots full of offsets in healthy condition of many kinds he will not be long before he establishes these also in quantity. In the years 1882 and 1883 Mr. Kavanagh carried all before him, and Mr. Tandy, who, as I have said, is no mean judge, assured me that (which I can readily believe) his plants were in superb condition. Is there any flower that so much excites the love of its owner as the Auricula? Who that has ever grown it likes to give it up? and Mr. Kavanagh is no exception to the rule. My only regret was that besides the plants I did not see the owner, who was described to me as a worthy and excellent man, and is without doubt an enthusiastic grower of this lovely flower.—D., Deal.

ROYAL HORTICULTURAL SOCIETY.

JUNE 24TH.

THE combined attractions furnished by the fruit and vegetables in competition for the numerous prizes, with the plants and flowers shown before the two Committees, constituted an exhibition of great beauty, and rendered the conservatory on that day the favourite and most frequented portion of the "Healtheries." Especially bright and charming were the hardy flowers which at recent meetings have been so much admired, and which were there even more beautiful than ever, the Irises alone supplying a feast of colour.

FRUIT AND VEGETABLE SHOW.

In accordance with the expectations which have been previously referred to, this second exhibition proved very satisfactory in every respect, the competitors being more numerous than at the preceding Show, and the quality of the produce, particularly in the Grape classes, being much in advance. In several classes indeed the exhibits were the best that have been staged at any of the leading shows this season, and it was doubly pleasing to see this Society's exhibition to the fore with the most useful of horticultural produce—fruit and vegetables.

Collections.—The most important class in the schedule was that for eight kinds of fruits, black and white Grapes to be regarded as distinct, the prizes being £7, £5, and £3. Three doughty champions entered the field, and premier honours were awarded to Lady Henry Somerset, Eastnor Castle (gardener Mr. Coleman), who had a beautiful even and excellent collection. The Grapes were Black Hamburg, large in bunch and berry, but slightly rubbed; and Foster's Seedling, unusually large in berry for this variety, but a little wanting in colour. A handsome Queen Pine, over 5 lbs in weight and well proportioned, was another strong point; Royal George Peaches, large and of good colour; Lord Napier Nectarines, very handsome; Brown Turkey Figs, well ripened; Bigarreau Napoleon Cherries, large and ripe; and a beautifully netted Blenheim Orange Melon, completed a most creditable collection. Mr. G. T. Miles, The Gardens, Wycombe Abbey, was adjudged the second prize for a collection very few points behind the other. His best fruit was a magnificent Queen Pine, weighing 6 lbs., finely proportioned and excellent in colour. Three good bunches of Gros Colman Grapes, weighing 6 lbs., were much admired, the berries being large and the bloom dense, but the Judges evidently gave the preference to the Black Hamburgs in the preceding lot. Mr. Miles's Foster's Seedling was much larger in bunch and of better colour, though the berries were smaller. Royal George Peaches and Lord Napier Nectarines were similarly notable dishes. H. A. Brassey, Esq., M.P., Preston Hall, Aylesford, Kent (gardener Mr. A. Waterman) was third with Black Hamburg Grapes, large and handsome; Buckland Sweetwater Grapes, very fine in berry; Elruge Nectarines, remarkably handsome; and a good Hero of Lockinge Melon.

Pine Apples.—Seven pairs of fruits were entered; J. A. Rolls, Esq., The Hendre, Monmouth (gardener Mr. Coomber), taking the lead with two even, handsome, finely ripened Queens. Mr. Miles followed with the same variety, 5½ lbs. each, but scarcely ripe enough; and L. J. Baker, Esq., Haydon Hall, Eastcote (gardener Mr. J. Fry), was third with small fruits.

Grapes.—A capital display of these was formed both in the black and white variety classes. For a basket of black Grapes to weigh 12 lbs. there were four competitors; Mr. James Tavener, Woolmer Gardens, Liphook, Hants, securing first honours with grand examples of Black Hamburg with enormous berries and bearing a most dense blue-black bloom, such as is rarely seen. The same variety was shown by the other exhibitors; J. Hargreaves, Esq., Maiden Erlegh, Reading (gardener Mr. T. Turton), being second with smaller bunches and berries and less bloom, but of good quality. Mr. Coleman was third with still smaller samples. The competition was keen in the class for two bunches of black Grapes, eight lots being staged. Again Mr. Tavener was far ahead of the others with Black Hamburg similar to those in the basket, really magnificent, and one of the bunches was characterised by one of the most experienced growers "as nearly perfect as could be imagined." Mr. C. Herrin, The Gardens, Chalfont Park,

Gerrard's Cross, was awarded second honours for good Black Hamburg, well ripened; and Viscount Eversley, Heckfield (gardener Mr. Wildsmith), was third with the same variety in fair condition. Six pairs of bunches of white Grapes were contributed, Mr. Herrin securing the leading place with Foster's Seedling, very handsome in bunch and berry. Mr. W. Bates, The Gardens, Poulett Lodge, Twickenham, followed with Buckland Sweetwater of good colour; and Mr. Tidy, The Gardens, Stanmore Hall, took the third position with Foster's Seedling, one of the bunches being very large.

Strawberries.—Some large and richly coloured fruits were shown in the three classes for Strawberries, though there was a tendency to coarseness in a few cases. The best of the five entries of three dishes was from Mr. Sharpe, the Royal Strawberry Gardens, Knowle Hill, Chertsey, which included large but somewhat rough fruits of Empress Eugenie, Marguerite, and Sir Joseph Paxton. The second prize went to Roger Leigh, Esq., M.P., Barham Court, Maidstone (gardener, Mr. C. Haycroft) for Duc de Magenta, President, and Sir Joseph Paxton, smaller, but of good colour. Mr. Turton was third with the two last-named varieties and Vicomtesse Hericart de Thury of fair size and colour. A class was provided for one dish (thirty fruits) of British Queen or any variety of that type, but only two were admitted, one lot of President being disqualified. Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, was first with British Queen, large and fine in colour; Mr. Goldsmith, The Gardens, Hollenden Park, Tonbridge, being second with Dr. Hogg of good size. For one dish of any variety W. E. Wells, Esq., Croxby House, Hounslow (gardener, Mr. G. Thompson), secured the premier award amongst seven other competitors with Sir Charles Napier, handsome in form and colour. Mr. Wildsmith followed with President, and Mr. Sharpe with Marguerite, both good samples of the varieties.

Cherries.—These made a pretty and pleasing display, the quality being very satisfactory. Mr. Roberts had the best two dishes, beautiful fruits of Elton and Black Tartarian. Mr. Haycock was second with Werder's Early Black and Elton, nearly as fine; and Mr. T. Hare, Wellingore, Grantham, was third, showing Black Circassian and Elton—three extremely close exhibits. Six dishes of fifty Cherries were staged, Governor Wood, from Mr. Waterman, leading; followed by Werder's Early Black from Mr. Haycock, and Elton from Mr. Hare, all fine fruits.

Figs.—Well-ripened fruits of Brown Turkey were entered by six competitors, Messrs. Wildsmith, Haycock, and Coleman being the prizetakers in that order, their fruits differing but slightly in merit.

Peaches.—These formed a remarkably strong class, as no less than seventeen dishes of six fruits each were staged. The Marchioness of Camden, Bayham Abbey (gardener, Mr. W. Johnston), won chief honours with extraordinarily fine fruits of Barrington, grand examples, and rich in colour. Mr. R. Farrance, Chadwell Heath, Essex, took the second place with Grosse Mignonne, very handsome, and Mr. Wildsmith was third for Crimson Galande, finely coloured.

Nectarines.—The same number of Nectarines were entered—i.e., seventeen dishes, Mr. Turton winning with Violette Hâtive of splendid colour. Mr. Haycock followed with Elruge in handsome condition, and the Earl of Leven and Melville, Fulmer, Slough (gardener, Mr. Mowbray), was third with Pitmaston Orange, also good.

Melons.—Competitors again numbered seventeen in this class, but much diversity was noticeable in the exhibits, some being excessively large and others proportionately small. Some exception was, however, taken to the judging in this class, owing to none of the fruits being cut. Mr. Mowbray won leading honours with Victory of Bristol, a beautiful even and well-netted fruit. Mr. Coomber was second with Best of All, similarly good, and Mr. Wildsmith took the third place with Hero of Lockinge.

Miscellaneous Fruits.—This was provided for Bananas, or any other fruits to which classes were not devoted. Mr. G. Thompson was awarded first honours for twelve pots of Strawberries, six of Sir Charles Napier and the same number of Sir Joseph Paxton. They were well fruited, bearing from two to three dozen each. Mr. Coleman secured the second prize for a dish of excellent Nonpareil Citrus of a fine golden yellow colour, and Mr. W. H. Ussher, 46, Lorne Terrace, Bath, was third for a beautiful dish of Bananas.

Collections of Vegetables.—Vegetables were capitally represented, fine, clean, and admirable collections of ten kinds being staged. Premier honours were secured by Mr. G. T. Miles for most praiseworthy samples of Stamfordian Tomatoes, Asparagus, Pride of the Market Peas, Moore's Cream Marrow, Erfurt Cauliflowers, Canadian Wonder Beans, Green Globe Artichokes, Lady Paget Potatoes, Nantes Horn Carrots, and White Naples Onions. Mr. Waterman was a close second, his best dishes being Stamfordian Tomatoes, Culverwell's Telegraph Peas, Canadian Wonder Beans, and Conover Colossal Asparagus. The Earl of Radnor, Coleshill House, Highworth (gardener, Mr. S. Haines), secured the third place with a clean and creditable collection, in which the Stamfordian Tomatoes were very notable.

Potatoes were strongly represented, eleven dishes of twelve tubers were shown; Viscount Barrington, Beckett Park, Shrivenham (Mr. W. Meads), taking the leading place with excellent samples of Woodstock Kidney; the Right Hon. Earl of Radnor, Longford Castle, Salisbury (gardener, Mr. Ward), was second with the same variety, and Mr. Miles was third. The best Cauliflower, Early London, were shown by the Hon. W. P. Talbot, Glenhurst, Esher (gardener, Mr. Waite), Messrs. Ward & Woodbridge following with Walcheren. Mushrooms were exhibited by Messrs. Haines, Tidy, and Coleman, who took the prizes in that order. Mr. Farrance won chief honours with Trophy Tomatoes, large and handsome, Mr. Miles following with Vick's Criterion.

Peas.—A great number of Peas were exhibited in the three classes devoted to them, and for the season they were all very good. With three dishes Mr. Ward was first, showing Carter's Stratagem, Telephone, and Telegraph, beautiful, even, and well-filled pods. Mr. Muir followed with Giant Marrow, Paragon, and Telegraph; and Mr. Waterman was third. Eight half pecks of Peas were staged, Mr. Haines leading with Stratagem, Mr. Muir and Mr. Nelson being second and third with Duke of Albany and William I. Mr. Muir gained the premier position with a collection of Peas, showing fine pods of Paragon, Pride of the Market, William I., Telephone, Giant Marrow, Telegraph, Jefferies' Edible-podded Pea, Duke of Albany, and Stratagem. Messrs. Haines and Ward were the other prizetakers.

With Broad or Longpod Beans Mr. Ward was first for Leviathan and

Seville Longpod, very fine specimens. Mr. Miles followed with the same varieties, and Mr. Steggle, Faulkners, Hadow, Tonbridge, was third with Aquadulce and Seville Longpod. The best Kidney Beans were Canadian Wonder from Mr. Waterman, followed by Messrs. Miles and Haines with the same variety. Carrots were well shown by Messrs. Waterman, Meads, and Miles, the varieties represented being French Forcing and Nantes Horn. Cucumbers were numerous, but not of remarkable merit, many being rather rough. Mr. Muir was first with a large collection of Lettuces, and the Right Hon. Earl Normanton, Somerley Park, Ringwood, obtained similar honours for a clean and excellent collection of salads, very tastefully set up.

Special Prizes.—Messrs. Webber & Co., Covent Garden, offered three prizes for the best packed three boxes of fruits—one box of Grapes, one of Peaches, and one of Nectarines. Mr. Turton secured first honours for very carefully packed samples. The Grapes were firmly placed together on tissue paper, covering a good padding of wool; the Peaches were separately wrapped in tissue paper and placed in dried moss in shallow boxes, one fruit deep; and the Strawberries were wrapped separately in Vine leaves in a shallow box. Mr. Coleman, who was second, had his fruit packed in a similar manner, but moss was employed as the padding in all the boxes. Mr. Eldridge, the Gardens, Chesterfield Park, Saffron Walden, was third, with similar examples of packing. Messrs. Wheeler & Sons, Gloucester, also offered a prize for samples of Kingsholm Cos and Tom Thumb Lettuces, and Mr. Muir was the only exhibitor, having very good specimens.

COMMITTEES.

FRUIT COMMITTEE.—Present: Henry Webb, Esq., in the chair, and Messrs. John Lee, G. M. Breese, G. Bunyard, J. E. Lane, C. Ross, W. Paul, R. D. Blackmore, J. Ellam, G. T. Miles, H. J. Veitch, J. Roberts, and T. C. Mundell. Melons were again largely shown, but they received no special recognition. Mr. Howe, Benham Park Gardens, Newbury, was awarded a vote of thanks for his Pink Perfection, a cross between William I. and Hero of Lockinge, a neat and well-flavoured Melon. Benham Beauty, from the same grower, was also attractive. Mr. Ross, Welford Park Gardens, showed a cross between Dickson's Exquisite and Hero of Lockinge, of good appearance. Mr. Wiles, Edgcott, Park Gardens, Banbury, sent a Melon named Hero of Edgcott, a cross between Eastnor Castle and Dr. Hogg, a large pretty netted fruit of fair flavour. Mr. Parr, Givons Grove, Leatherhead, also sent a sample of the Goodwood Melon, which weighed 14 lbs. 2 ozs., but it was not to be cut, so no opinion could be formed as to its merit. Mr. Roberts, The Gardens, Gunnersbury Park, sent three bunches of Duke of Buccleuch Grapes, with the object, as was explained in a letter, of proving that this variety can be grown free from spot. The berries were large and perfectly clean, their condition being most satisfactory, and Mr. Roberts well deserved the cultural commendation awarded for them. The Committee also expressed a desire to see them again. Mrs. Spottiswoode, Coombe Bank, Sevenoaks (gardener, Mr. Bolton) showed branches of Bolton's Prolific Gooseberry, which were bearing a fine crop of rather small berries.

FLORAL COMMITTEE.—Section A. Present: Mr. John Fraser in the chair, and Messrs. H. Ballantine, H. Williams, F. R. Kinghorn, E. Hill, J. O'Brien, J. Woodbridge, the Rev. G. Henslow, and Dr. M. T. Masters. Section B. Present: Shirley Hibberd, Esq., in the chair and Messrs. H. Caunell, W. Bealby, G. Driffild, and H. Turner.

A choice collection of Tree Carnations, Pinks, and Pelargoniums was contributed by Mr. C. Turner, Slough, for which a vote of thanks was accorded. Of the Tree Carnations, the beautiful rose self, Mrs. Llewelyn, and the pure white Water Nymph, were very notable, both being useful free varieties of strong habit. Several of the Pinks were very handsome, and one was certificated. Of the Pelargoniums, an effective Show variety was The Czar, which has scarlet lower petals, the upper darker, and the centre white. Boira was a similar type, but with white and crimson petals, very pretty. J. T. D. Llewelyn, Esq., Penllergare sent three pretty Primulas—namely, *P. suffruticosa* of half-shrubby habit, with small leaves and diminutive pink flowers; *P. luteola*, one of the *P. sikkimensis* type; and a dark variety of *P. capitata*. Mr. H. Bennett, Shepperton, was accorded a vote of thanks for boxes of "Pedigree" Roses and others, very beautiful being Princess of Wales, the Earl and Countess of Pembroke, Lady Mary Fitzwilliam, and Grace Darling. A vote of thanks was accorded to Messrs. Laing & Co., Forest Hill, for a charming group of single and double varieties of Tuberous Begonias, representing a number of distinct novelties, several of which were certificated. A collection of Verbena blooms from Mr. Stacey, Dunmow, Essex, was similarly recognised. Mr. Aslett, Warren Wood, Hertford, sent some fine double Begonias; and Mr. G. Prince, Oxford, had several boxes of fresh and beautiful Tea Roses, large and of the usual quality distinguishing Mr. Prince's exhibits of that kind. Especially notable were Catherine Mermet, Etoile de Lyon, Comtesse Naudillac, and Alba Rosea, the last being grown in large quantities at Oxford. A vote of thanks was accorded to Mr. Pollett of Bickley for a small collection of well-grown Orchids; and from the Royal Horticultural Society's Gardens at Chiswick were sent some pretty Begonias, a plant of the noble Saxifraga longifolia with a grand panicle of flowers, two pans of Orchis foliosa with six and eight spikes each, Mimulus, and the violet-coloured Toronia Fournieri in first-rate condition. Messrs. James Veitch & Sons, Chelsea, and Mr. B. S. Williams, Upper Holloway, exhibited several beautiful new Orchids and other plants, which were certificated.

An extensive and charming collection of hardy flowers was shown by Messrs. Veitch & Sons, comprising Irises, Pyrethrums, Ixias, the useful Gladiolus Colvilli alba, G. byzantinus, and a fine strain of Sweet Williams, for which a bronze Flora medal was awarded. Similar groups were contributed by Messrs. Barr & Son, Covent Garden, and Mr. T. S. Ware, Tottenham, for which a silver Banksian and a silver-gilt Flora medal were respectively awarded. The Tottenham group was particularly handsome, and it is doubtful if a more effective collection of hardy flowers has ever been shown. Messrs. Hooper & Co., Covent Garden, and Messrs. Kelway & Son, Langport, also staged collections of beautiful Gladiolus, Irises, and Pyrethrums, which furnished additional attractions to the Show of considerable value.

First-class certificates were awarded for the following plants:—

Rhododendron President (Veitch).—One of the greenhouse hybrid class, and a magnificent form. The flowers are particularly large, grand tubes 2½ inches across at the mouth, with rounded lobes. The colour is a

yellowish buff with a slight pinkish margin to the lobes, the heads containing six flowers.

Drosera auriculata (Veitch).—A peculiar species, with slender trailing or climbing stems, and diminutive round leaf blades somewhat like a small form of *D. rotundifolia*, but quite different in habit.

Philodendron grandidens (Veitch).—A handsome foliage plant, the leaves sagittate, of a bronzy green hue with a velvety surface 18 inches long by about 8 inches or 9 inches broad.

Odontoglossum excellens (Sir Trevor Lawrence).—An extremely distinct and beautiful Orchid; sepals yellow with bars of chocolate, petals with a white centre margined with yellow, lip white with a few brown blotches.

Odontoglossum Alexandræ Veitchianum (Baron Schröder).—A grand variety, similar to Messrs. Veitch's mirabile. The flowers are beautifully formed, having broad sepals and petals white, with a faint band of pale purple near the margin, and a few chocolate spots.

Lælia Dominiana rosea (Baron Schröder).—Remarkable for the deep crimson colour of the slightly fringed lip, and rosy colour of the sepals and petals.

Anguloa Ruckeri sanguinea (Crawshay).—Distinct from the ordinary *A. Ruckeri* in the darker purplish crimson colour of the inner portion of the flower, which is greenish externally.

Odontoglossum Williamsianum (Williams).—Described as a hybrid between *O. grande* and *O. Schlieperianum*. A most distinct and handsome form, with bold flowers 4 inches across, the petals being 1½ broad, blunt and rounded, the upper half clear yellow and the lower brown. The sepals are barred with brown on a bright yellow ground, the lip being of a paler ground colour with a few brown spots. The spike was a strong one bearing twelve flowers.

Lælia purpurata atro-purpurea (Williams).—A handsome richly coloured variety, the lip being of a very dark crimson hue.

Croton Flambeau (Williams).—A graceful narrow-leaved variety. The leaves 1 inch broad and about 18 inches long, deep red, and dark green mottled with yellow. Elegant in habit, and colours well in a young state.

Tea Rose Sunset (W. Paul & Son).—Very fragrant; blooms full, orange yellow in the centre, lighter on the outer portion of the flower.

Odontoglossum citrosum, pure white variety (Dr. Soper).—Flowers of good size and pure white.

Verbena striata (Stacey).—A neatly shaped variety; flowers large, white, with regular stripes of pink.

Tuberous Begonia Her Majesty (Laing).—Single; very handsome and distinct. Flowers of great size and excellent form, white, with a pink margin.

Tuberous Begonia Torey Laing (Laing).—Single. Orange yellow; free and effective, a useful and charming variety.

Primula capitata Hooker's variety (Llewelyn).—A beautiful variety, with much darker violet-purple flowers than the ordinary form.

Pelargonium purpureum (Turner).—A Show variety with superb flowers; broad handsome petals, the lower ones pink and the upper dark maroon, with a white centre.

Pink picturatus (Turner).—A most attractive variety, with well-formed flowers; the petals white, heavily laced with pale purple. Very free and useful.

SCIENTIFIC COMMITTEE.—Mr. A. Grote in the chair.

Photographs of Araucaria imbricata (male) and *Chamaerops excelsa*.—Mr. Farrant of Ballamoor, Isle of Man, sent excellent photographs of these trees. The former was the one alluded to in the last meeting, and bearing an extraordinary number of male catkins. The latter, Mr. Farrant says, has flowered profusely and continuously for the last ten years, and has never been affected by the severest frost.

Fusisporium microphytum.—Mr. W. G. Smith exhibited drawings of this fungus with brown spores, growing on the gills of Agaricus. The question was raised whether it was epiphytic or truly parasitic. It also grows on the gills of the bedding Mushroom.

Saprolegnia mucophaga (W. G. Smith).—Mr. Smith proved by cultivating in water the well-known white mould familiar on the gills of bed Mushrooms, that it was a new small species of Saprolegnia, which he proposes to call *S. mucophaga*.

Sphaerella Taxi.—Hon. and Rev. Mr. Boscawen sent specimens of Yew attacked by this fungus about six years ago. It has now travelled as far west as Dorset, and is destroying the Yew trees at Sherborne.

Acidium convallariæ.—Mr. Smith also exhibited specimens of this fungus, new to England, and which was seriously injuring the Lily of the Valley in Westmoreland, and which he thinks is very likely to spread to cultivated Lilies.

Tragopogon.—Dr. M. T. Masters exhibited a specimen of *T. pratense*, in which the florets were all "tubular" instead of being "ligulate," and the pappus sub-foliateous.

Fasciated Scrophularia.—Mr. Houston brought a tall and fine fasciated stem of this plant.

Potato Disease.—Mr. Laxton of Bedford reported the first and very early appearance of the Potato disease at Bedford.

Amanita Pantherinus.—Mr. Boulger showed an instance of a specimen gathered some days ago, and which, being confined horizontally in a tin box, had become erect by apogeotropism.

Double White Rocket.—Mr. Loder exhibited a fine pure white specimen for contrast with the lilac-tinted variety grown on the continent.

Dianthus alpinus crossed with D. barbatus.—He also exhibited blossoms of this hybrid, which at first were white like the female parents (a white var.), and then turned to deep crimson subsequently. *D. alpinus* crossed by *D. superbus* was shown by Professor M. Foster, in which the silky appendages of the petals had almost entirely disappeared. Mr. Lowe remarked that some starved specimens of *D. alpinus* were not distinguishable from *D. deltoides*.

Ulex nana var.—Mr. Lowe described a plant with prodigious thorns, resembling a *Colletia horrida*.

Irises.—Professor M. Foster exhibited a large and interesting series of Irises, the results of his crossings, &c. Of original species were *I. kumaonensis*, but not the typical bright blue. It belonged to the *Diets* section, and seemed allied to *I. nepalensis*. It had roots like that of *Hemerocallis*. *I. plicata* crossed by *I. variegata* var. The produce differed very materially from both parents. Seedlings of *I. ochroleuca*, mostly lilac-tinted, but a

few were yellow, like the type. *I. variegata* (yellow) crossed by *I. pallida*. One seedling was pure white, quite unlike the parents.

Iris hexagona.—Mr. Lynch sent a specimen of this species from Florida, and which flowered for the first time at Cambridge. It had long sepals, greenish externally, and lilac petals.

Monstrous Digitalis.—Rev. J. Henslow exhibited a monstrous blossom of a kind not uncommon in the Foxglove. The bracts below the terminal flowers graduated into sepals, four of which were half-petaloid. The corolla had a regular tube with fifteen lobes, but was split down one side, and carrying thirteen stamens; within the tube was a gamosepalous calyx of seven sepals, and which contained an irregular mass of abortive virescent or partly spotted petals mixed with stamens. Within this was a similar structure. The repetition of calyx, petals, and stamens is somewhat similar to some kinds of double Daffodils and the double *Helianthemum vulgare*.

Monstrous Antirrhinum.—Mr. James King, of Rowsham, Aylesbury, sent some remarkably malformed Snapdragons, called the "Rowsham Pet," and which received a second-class certificate. It showed a tendency to be polypetalous, but with a multiplication of parts of the corolla as well as of the stamens. It was abortive, but propagated by cuttings. It was referred to the Rev. G. Henslow for further examination and report.

Clematis.—Mr. Noble sent a *Clematis* called "Proteus," which, after producing very double flowers at the end of June, rests for a month and then flowers again, as is the habit with other kinds, but differs from the latter in bearing single blossoms only. This was the case in 1883.

COMING FLOWER SHOWS.

EXHIBITIONS are as numerous as ever, the following being those for June, July, August, and September, of which we have received any notification at present:—

- June 26th.—Richmond. Canterbury (Roses).
- " 28th.—West Kent. Camden Park, Chislehurst. Reigate (Roses).
- July 1st.—Edinburgh International Forestry Exhibition. National Rose Society, South Kensington. Stoke Bishop.
- " 2nd.—Royal Botanic Society's Evening Fête. Hull (three days). Wimbledon. Cardiff.
- " 3rd.—Bury St. Edmunds. Winchester (two days). Bath (Roses). Chiswick. Farnham (Roses).
- " 4th.—Sutton (Roses). Tunbridge Wells.
- " 5th.—Crystal Palace (Roses).
- " 7th.—Brockham (Roses).
- " 8th.—Royal Horticultural Society, Fruit and Floral Committees; Promenade Show.
- " 9th.—Edinburgh (two days). Salisbury (Roses). Lee (two days).
- " 10th.—Oxford (Roses).
- " 14th.—Wolverhampton (three days).
- " 16th.—Bedford.
- " 17th.—Carlisle (two days). Warkworth (Roses). Newport.
- " 19th.—Manchester (Roses).
- " 22nd.—Royal Horticultural Society, Fruit and Floral Committees; Fruit and Vegetable Show; Carnation and Picotee Show.
- " 23rd.—Newcastle-on-Tyne (three days). Feltham.
- " 24th.—Sheffield (two days).
- " 30th.—Warwick.
- August 2nd.—Liverpool (two days). Southampton (two days).
- " 12th.—Royal Horticultural Society, Fruit and Floral Committees; Cottagers' Show.
- " 14th.—Maidenhead.
- " 20th.—Shrewsbury (two days).
- " 21st.—Reading.
- " 26th.—Royal Horticultural Society, Fruit and Floral Committees; Fruit and Vegetable Show. Banbury.
- September 2nd.—Stratford-on-Avon (two days).
- " 3rd.—Glasgow. Bath (two days).
- " 5th.—Crystal Palace Fruit and Dahlias (two days).
- " 9th.—Royal Horticultural Society, Fruit and Floral Committees.
- " 11th.—Bury St. Edmunds (two days). Dundee International (three days).
- " 17th.—Edinburgh (two days).
- " 25rd.—Royal Horticultural Society, Fruit and Floral Committees; Fruit and Vegetable Show.

HARDY FRUIT GARDEN.

Watering.—Now that the crop of fruit of all kinds is set and swelling it is important that the growth should be free and unchecked; there must, therefore, be no lack of moisture in the soil to afford a prompt and steady supply of food for the root-hairs. Upon the nature of that moisture depends the development of leaf, branch, and fruit; clearly, then, it should contain nutriment in a much larger quantity than water affords. We have, however, only to take the best substitute for it—house sewage—and we have a mild form of liquid manure that is safe in the hands of the most ignorant labourer. With the sound system of drainage and thorough mechanical division of the soil which we have so long and so persistently advocated, there is no danger of harmful application of sewage; and we have only to take care that enough is used regularly to keep up an ample store of fertility in the soil, with the comfortable assurance that no harm can happen from any careless excess in its use. Need we add the other important consideration, that the use of house sewage is true economy? Owners of gardens should see that there is enough labour power in the garden to insure the regular use of

the sewage—no light matter at so busy a season of the year. It is simply ridiculous to provide a cesspool, pump, and piping without affording the gardener enough helps to turn it to account.

The Foliage.—By midsummer the foliage necessary for sap-elaboration is fully developed, and its vital functions are in full activity; cleanliness and freedom from blight or insect ravages is therefore most important. Clean water forced upwards among the leaves by a powerful syringe or garden engine occasionally is good practice, tending, as it does, to keep under red spider and dislodge other insects. Aphides upon Cherry shoots are easily got rid of by dipping each shoot in tobacco water, made by steeping 4 ozs. of tobacco in a gallon of water. Let the dipping be done on a calm dry evening, and syringe with clean water on the following morning. Caterpillars on Gooseberry and Currant leaves should be picked off by hand and killed. Avoid the dangerous plan of dusting the bushes now with powdered hellebore to destroy the caterpillars; the powder is a deadly poison, which might be eaten with the fruit and cause loss of life.

Strawberries.—The layering of runners for new beds should be done as soon as possible, in order that the plants may be ready for planting in July or early in August. The best way of doing this is to fill enough 3-inch pots firmly with old well-decayed hotbed manure, sink each pot to the rim in the ground with a trowel, peg the runner carefully upon the middle of the soil in the pot, and it will root quickly and well. By plunging the pots little, if any, watering is required, the cool soil around the pot checking the excessive evaporation, which is unavoidable when it stands upon the surface fully exposed to the heat of summer. Pieces of turf are sometimes recommended in preference to pots for this purpose, but we prefer the pots because they are ready to our hands, and every aid to time-saving now is important. Early summer planting means half a crop of fine fruit early next year; late summer or autumn planting of late-rooted runners means no fruit till the year after next. Even if you cannot plant early in the permanent beds, by all means secure a supply of the earliest runners, which may be planted thickly in borders and transplanted when space can be afforded them, and so get a little fruit next year.

Raspberries.—Thin new growth, and give the entire surface between the rows heavy waterings of sewage, both to assist the swelling fruit and to promote strong growth for next year's crop. Currants, Gooseberries, and American Blackberries all have sewage regularly too. The entire plantation has a surface dressing of farmyard manure, which keeps down weeds, attracts the roots to the surface, feeds them, and also acts as a mulching to check evaporation.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Early Houses*.—Directly after the removal of the fruit from the trees means must be adopted for cleansing the foliage by frequent washing with the garden engine. The free exposure of the present year's growths by taking out the shoots that have borne fruit, and such as are not likely to be wanted for affording fruit next season, should also be attended to. Where this operation is judiciously performed little pruning in autumn will be required, and the young growths having had full exposure to sun and air will be thoroughly ripe, firm, and well furnished with fruit buds. Let inside borders have liberal supplies of water, affording liquid manure to trees that have been heavily cropped and show signs of exhaustion. Mark such as need lifting to check any tendency to over-luxuriance, or to add fresh loam to such as show signs of failing vigour. Nothing pays better in Peach culture than frequent lifting. The best time to perform the operation is just before the leaves fall, and being carefully performed the trees rarely cast their buds, the fruit rarely fails to set and stone well, and swell off good crops of fruit. Lifting or bringing the roots near the surface, especially when performed before the fall of the leaves, causes a free production of active surface roots, which to the early forcer are a great gain, as the trees make a quick response to the application of heat when the house is closed for forcing.

The earliest-forced house may now have the roof lights removed, but it is advisable to do this by degrees rather than exposing the trees at once to the open air; and in the case of trees that are very vigorous the lights will need to be kept on some time longer than those that have firm short-jointed growths.

Succession Houses.—The fruit of plants started in February will now be ripening, and will need a drier condition of the atmosphere with a free circulation of air. A gentle damping of the borders will be needed occasionally for the benefit of the foliage, and the trees must not be allowed to become dry at the roots. Trees in late succession houses that have passed the stoning process should be examined carefully, and all pendent fruit that can be turned up to the light and supported apex upward on laths placed across the wires forming the trellis. Stop the points of the shoots carrying fruit, otherwise allow a fair extension, but gross growths should be pinched so as to equalise the sap as much as possible. Avoid overcropping; a fruit to every square foot of surface is ample where size and quality is the first consideration, and timely thinning to that quantity will not only increase the size of the fruit but prevent any being cast through the process of stoning, which is the most trying for the trees in the whole of the forcing or growing period. Syringe freely twice a day until the fruits begin to soften or ripen, using clear soft water, as water that is hard often stains the fruit. Avoid a close moist atmosphere at night by giving air then or very early in the morning, and run up to 80° in the afternoon with sun heat after closing.

Late Houses.—Keep the trees thin of wood, not allowing more shoots to remain than will be necessary for the next year's crop or furnishing the trees. This is absolutely necessary to secure short-jointed thoroughly

solidified growth, and insure their thorough ripening. The growths should be closely tied in or down as they advance, and the fruit thinned in good time, so that those left for the crop may have the fullest support. Water the borders freely, and mulch with short manure to keep the roots active near the surface. Ventilate freely in the early part of the day, and reduce the ventilation early in the afternoon, rising to 80° from sun heat if the fruit is desired accelerated, otherwise admit air constantly if it be wished retarded in ripening.

Melons.—Under ordinary circumstances fire heat can usually be dispensed with by the middle of June, but the nights are still so cold in some districts that heat is absolutely needed to maintain a suitable temperature. See that former instructions in stopping are attended to, also thinning, tying, and otherwise arranging the fruits, which should be regularly attended to, as any neglect in these matters is certain to tell disastrously in the results. Earth-up successional plantings as soon as the roots push through the hillocks. Supports must be placed to the fruits as they require them. Examine the plants at least twice a week, seeing that they do not suffer from insufficient or too much water. Plants that are swelling their fruits should have generous treatment; when they need watering give them a good soaking of tepid weak liquid manure.

The earliest plants that were retained after the first crop will now be ripening their second crops, and will need to be kept somewhat drier and more freely ventilated. This applies equally to all houses with the fruit ripening, also to plants in pits and frames.

Pits and Frames.—In a dull cold period the plants often suffer irreparable injury, which timely attention to the linings would have prevented, as with a genial heat a little air could have been given so as to prevent damage from an accumulation of damp, resulting in canker, the non-setting and imperfect ripening of the fruits. In order to insure a good set promote a circulation of air, and have the bed dry, keeping the growths thin, and fertilise the flowers daily as they expand, stopping the shoots at the same time one joint beyond the fruits. Commence ventilating early, and close as soon as safe in the afternoon, sprinkling plants swelling off their crops at closing time.

Strawberries in Pots.—The recommendation of varieties that are best adapted for forcing is very often vague from it not being defined for what purpose the fruit is intended. For home use soft fruits answer very well, and Keens' Seedling is a great favourite, so is Marguerite, but these soft fruits travel badly. For forcing it is essential that the fruit be large and of fine appearance, and those that answer this description are La Grosse Sucrée, Vicomtesse Hericart de Thury, well thinned; and for second earlies Sir Harry, President, and Mr. Radclyffe; for late use James Veitch, Sir Charles Napier, Dr. Hogg, and Cockscumb. The runners should be laid as soon as they are obtainable in small pots in good loam, with a sprinkling of horse droppings, drawing the runners of two lines into one to save labour, and the pots are best plunged so as to lessen the necessity for watering and keep them in position. The runners, it is needless to state, should be taken from young vigorous plants—those from plants put out last summer are best—and they should be taken only from fruitful plants.

PLANT HOUSES.

BEGONIAS.—*Begonias manicata*, *Ingramii*, *Knowsleyana*, and others for autumn and winter-flowering will now be established in small pots. If well rooted place them in 5-inch pots, and grow them on in frames where an intermediate temperature can be maintained until they are rooting freely in the new soil. When thoroughly established they may be gradually hardened and grown for the summer months under cool-frame treatment, in which position they will do much better than in heat.

Begonia semperflorens.—The earliest batch raised from seed will now be in full beauty, and can be used for decoration in the conservatory, where they will continue to bloom for a long time if artificial manure is applied to the surface occasionally. Young plants established in 3-inch pots should be placed into 5-inch pots, and grown until they come into bloom in cold frames. For decoration all the year round no better *Begonia* can be grown. A little seed should be sown to supply plants for autumn and winter-flowering. The seed must be sown on the surface of fine soil in a pan or pot, carefully watered and covered with a square of glass until it germinates.

Begonia parviflora* and *B. Dregei.—For summer decoration these are useful plants, and either may be grown, for they are very much alike. We prefer the last named. Anyone only having a greenhouse may grow either of these varieties to perfection, for when once they commence flowering they will continue to do so for months. They are useful for autumn and winter, but soon draw up weakly in stove heat, therefore we employ them only for summer decoration. Under cool treatment our plants are now in full beauty. If necessary to increase the stock of these varieties cuttings will root with great freedom in sandy soil in gentle heat, and will make by autumn fine little plants for ripening off for another season. *B. weltoniensis* requires the same treatment, and is a grand variety for the conservatory at this season of the year. Good loam, leaf soil, a seventh of decayed manure and sand will form a good compost for growing these plants in.

Tuberous Varieties.—These are amongst the most beautiful of plants, and the easiest of all to cultivate, and will, without doubt, be grown in future largely for decoration indoors in preference to Zonal Pelargoniums at this season of the year. Those brought forward in heat will be in full beauty, while those started under cool conditions will be developing strongly and vigorously. If these plants are young and leading away

with single stems pinch the top out of them, and they will break freely a number of shoots from the lower eyes of the stem. Some varieties branch without stopping, while others will not; and in order to have well-developed shapely plants for decoration in 6, 7, or 8-inch pots, stopping should be resorted to. When pinching is practised it requires longer to get the plants into flower, and should not be practised when the plants are wanted in bloom as early as possible. Grow in cold frames, and give abundance of water at the roots when the plants are growing vigorously. These plants must be carefully and judiciously shaded, for they cannot endure strong sunshine.

THE BEE-KEEPER.

THE DEPOSITION OF QUEENS.

My anticipations some weeks since that queens in stock hives would be deposed, from the continued strain upon their system through prolonged breeding during this untoward season have in many cases been verified, so that instead of the old queen accompanying the swarm, as she is commonly understood to do, a young one, or perhaps many, will issue. If more than one queen joins the swarm they do not settle readily, and when hived are liable to abscond, so that attention should be paid to swarms of this sort. The old queen is generally not deposed until a young one is hatched, so that the old queen deposits eggs to within a day or two of swarming. If the weather is fine there is no great loss, because the young queen will, if fertilised, lay more eggs than the old one would have done; hence after three weeks the hive is in a better condition, but there is a possibility she will remain sterile for a considerable time. If the weather is dull there is the risk of her being lost in her wedding flight, which if unobserved the hive would be lost. To prevent ruin and disappointment, and secure strong and profitable hives, strict attention should be paid to both stock and swarms for some days after. If the weather continues unfavourable, fertilised queens should be joined from the nuclei in reserve, and the unfertilised ones joined to them. This no doubt will cause a little trouble, but prevents mishaps and disappointment. When overhauling hives at this time under these circumstances superfluous drone combs should be excised, keeping a strict look-out to detect foul brood. If present take the necessary steps to get rid of it, for depend upon it, it is not to be trifled with, while bees breed better and are healthier in new combs than in old ones, the former being easier warmed than the latter during early breeding in spring.

Supers.—It is not a bad plan to super hives that are a little late in swarming, because it does not delay them; and such supers, if not too large and the weather fine, will be filled in a few days, and then finished in all its purity by old stock, whose bees are not as numerous after as before swarming. During dull rainy weather unfinished supers are very liable to be discoloured, from the bees crowding on them, which is not preventible unless removed and replaced when weather becomes favourable. With hives fitted with slides, such as the Stewarton, discoloration of the combs is easily prevented by the regulation of them. Remove all supers when sealed, and as long as the bees care to build comb, giving air from beneath during hot days, contracting at night if at all cold. Giving plenty of room, keeping the hive shaded and the supers well covered, is about all that is required this month, providing the other foregoing precautions have been taken.

Feeding.—At no time of the year is food more necessary than now if honey is scarce, but it should not be given in greater quantity than to encourage breeding and comb-building in hives not full, and prevent the drawing of eggs, grub, and young bees, which is sure to take place if hives are allowed to approach starvation. The quantity of sugar required depends upon the number of bees and state of the hive with combs. Those that are required for stock hives can be more liberally fed than those intended for honey, where it would be dishonest to give the bees sugar to store, then sell as honey. With such hives a quarter of a pound every night will be about enough to tide them over till honey is plentiful, which will come with settled weather and flowers now appearing.—A LANARKSHIRE BEE-KEEPER.

STEWARTON HIVES.

Your talented correspondent, "Lanarkshire Bee-keeper," is evidently an advocate of the Stewarton hive; he also refers to the advantage of a possible harvest from Heather.

As a keeper of bees in Stewartons, residing about ten miles from extensive moors, I should be very much obliged if he would give detailed instructions as to moving of bees in these hives to the moors, and as to the advisability of the risk with the enormous population in body boxes, ckes, and supers that these non-swarming hives invariably have in autumn. I conclude that "Lanarkshire Bee-keeper" would admit the distinct risk

under ordinary circumstances, with ordinary conditions, and on a favourably balanced spring cart.—F. W. S.

Will "Lanarkshire Bee-keeper" please give a detailed statement, with exact measurements, for making Stewarton hives, supers for same, and all other connections? Having seen and heard many statements of the advantages of those hives over others, I would like to try them, but do not know how to proceed. Which is the best way to find a queen bee in a hive or in a swarm? I have searched over three second swarms and carefully examined a bar-frame hive and could not get a sight of her. How should the search be conducted?—NOVICE.

"THE AMATEUR'S GUIDE TO BEE-KEEPING." By A. G. Dawson. Manchester: Geo. Falkner & Sons.—This is a small 4to. pamphlet by Mr. A. E. Dawson of Macclesfield, which treats of bee-keeping in a plain, intelligible, and concise manner, and is copiously illustrated by well-executed engravings of the various kinds of bees and the most approved apian apparatus. It will be very useful to beginners, as the instructions are not treated in a diffusive manner nor yet too technically, and the only omission we note is that Mr. Dawson has not given any instruction about "supering." This is a subject which puzzles beginners, and one of the questions we are most frequently asked is, "When must I put on supers?" No doubt Mr. Dawson will supply this in a subsequent edition. There is a very ample catalogue at the end of all kinds of hives and apparatus.

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Pruning Ivy and Evergreens (*E. R., Bromsgrove*).—The worst time to cut Ivy on walls is just before "the cold weather sets in" in the autumn, as then the walls are bare and unsightly for months, besides exposing the stems to the action of possibly severe frost, and we have known them killed by such exposure. The best time to cut it is during showery weather towards the end of April or early in May, as then fresh growths appear at once, and a cheerful glossy face is produced. Once in three years is usually sufficient for shaving off Ivy close to the walls to which it clings, during the intervening years the runners simply being cut off with a knife, leaving the principal foliage. We know Ivy that has been thus managed for half a century, and in all probability more than twice that time, and it is in the most satisfactory condition. If evergreens need cutting down below the foliage, early spring is the best time; if the shrubs only need trimming into shape the work may be done at any time now until September.

Pelargoniums—Vines (*H. S.*).—The soiled condition of the Pelargonium leaves has not been caused by the Fir-tree oil, but by the insects against which it was applied. It is simply the filth of the pests taken possession of by a fungus, and there is no method of cleaning the foliage except with a sponge and soapy water. Shortly, however, the plants will be ready for cutting down, and if the shoots are severed, as they should be, below the leaves, you will effect a radical cure. Had the insects been prevented by timely syringings or fumigation there would have been no unsightly black patches on the leaves. You may cut down the Lemon-scented Verbena in the same manner as the Pelargoniums, or plant it out, when the fresh growths will be clean. It is quite impossible for anyone to give you a categorical reply to your question about the Vines without some knowledge of their actual condition. They may possibly have been rather overcropped last year, and the growths, perhaps, somewhat overcrowded and not satisfactorily matured. The laterals should be sufficiently far apart for the foliage to develop under the full influence of the sun, while at the same time as many leaves as possible should be allowed provided they do not overlap each other. On this principle, the roots of course being right, strong growth is insured, and with sufficient heat and air in the autumn matured wood, and strong, well-fed, matured wood is sure to produce good Grapes. A little fire heat in the autumn after the crop has been cut is often of great advantage in promoting the fruitfulness of Vines, and especially in cold northerly districts.

Outdoor Mushroom Beds (*S. L. B., Liverpool*).—Sawdust containing 70 to 75 per cent. of horse droppings, mixed with the equal quantity of straw manure, will answer admirably, provided you can make the ridges firm enough and the angle sufficiently acute to throw off the wet, and this we think you might accomplish by using a less quantity of sawdust with the manure for

the outsides of the beds, or a larger portion in the inside would be permissible. If woodlice are very numerous they are injurious to Mushrooms. You will soon find out whether they devour yours or not. They are not very easy to destroy, but they will not congregate in large numbers if you keep the material that covers the beds moist with an occasional sprinkling of salt and water. Woodlice object to this and Mushrooms do not, provided not more than an ounce of salt is mixed in each gallon of water. It may be well, perhaps, to intimate that this is about the worst period of the year for making outdoor Mushroom beds unless their position is exceptionally cool.

Azalea Flowers Malformed (*W. W. W.*).—It is by no means easy to indicate the cause of the petals of the flowers splitting in such an extraordinary manner. You say nothing about the condition of the plants nor the treatment to which they have been subjected, except indicating the temperature of the house in winter, and that we can assure you has had nothing to do with the case. It may be a consequence of immature growth, coupled with an accident in allowing the plants to get too dry when the flowers were forming, thus causing a withering and shrinkage of the petals when in an incipient state. This is the only suggestion we can offer in the absence of sufficient data to enable us to comprehend the condition of the plants.

Peaches and Nectarines Falling (*J. F., Godalming*).—The origin of the evil we attribute mainly to the powerful fumigations to which you allude at a critical period—namely, about the stoning time. Tobacco smoke in sufficient strength to kill the black aphid temporarily paralyses the trees, and the effect of this is seen sooner or later in falling fruit. Every endeavour should be made to prevent the insects getting established, and this can usually be accomplished by the free use of the syringe and such insecticides as may be needed for the purpose. The frost, if severe at the time you name, would aggravate the evil, but we can scarcely think it was so intense as to have such disastrous results; you do not, however, indicate its severity.

Proliferous Pelargonium (*E. O., Bishops Stortford*).—The moment the truss was removed every petal dropped—in fact, they nearly all of them were on the bottom of the box when the lid was removed. This is invariably the case when the petals are not sealed by touching the centre of each flower with a little clear gum. We are unable, however, at any time to undertake to name varieties of Pelargoniums or other florists' flowers, as they are far too numerous and too closely resembling each other for anyone to do so without comparing them with others in a large collection. Proliferous trusses are usually caused by too rich and insufficiently firm soil. Turfy loam with about a seventh part of decayed manure, and a little gritty matter is a suitable compost, and should be pressed into the pots as firmly as possible, many successful growers using a blunted stick for that purpose.

Soiled Foliage (*J. W.*).—The "smut" on the leaves of your "Myrtles, Orange trees, and other evergreens" in your house is the direct result of insects. The plants are probably infested with scale, if not with other insects, or plants above them are infested and the filth falls on the leaves below. A fungus then takes possession of it, and not only renders the plants unsightly, but impairs their health. They can only be thoroughly cleansed by sponging with warm soapy water, but some of the filth may be removed by forcible and frequent syringings. Half a wineglass of petroleum mixed with a gallon of water containing an ounce or two of softsoap in solution, and applied with a syringe, will destroy scale and most other insects, but should only be used during the evening, as if the sun shines on the plants before they are dry the leaves may be injured. It is a great mistake to allow plants to get into such a bad state, as much labour is involved in cleansing them.

Various (*Mrs. D.*).—We fear the ventilation of house containing the Vines and Peaches is defective, and we also suspect that the best has not been made of the means afforded for regulating the temperature. The warted appearance of the Vine leaves is the result of extreme evaporation, such as occurs when a house is kept closed too long in the morning and then the ventilators thrown widely open, as if to atone for the previous neglect or forgetfulness. The more limited the means of ventilation the earlier the lights should be opened. You do right by closing early, but an hour or two afterwards we should open the top ventilators slightly, leaving them open all night, and then give additional air within half an hour of the sun reaching the house in the morning, whether that occurred at six o'clock or earlier. The Peach trees are also suffering by want of early ventilation, hence the want of substance in the leaves and the attack of mildew on the fruit. There were evident signs of red spider, which seldom fails to attack enervated trees. Syringe them heavily twice a day until the fruit shows signs of ripening. Do not close the ventilators at night; open them earlier in the morning, and admit all the air possible before the maximum day temperature of the house is reached. There is nothing particularly the matter with the Sparmannia. There are a few insects on the leaves, which are also too pale in colour. Prune the plant slightly if needed, remove some of the old soil from the roots and add fresh, and as soon as fresh roots take possession of the new soil give clear soot water twice a week. The plant may be stood on ashes or other base impervious to worms in the open air, at first in a shaded place for a week or two, then where it can have sun, but shading the pot, this latter precaution being important in hot weather. Narcissuses can only be forced successfully a second year when great care has been bestowed on the plants in the production of good foliage under the influence of light and air after the flowers faded. This is seldom done, often because there is not a suitable position for the plants after flowering, and as a rule it is advisable to procure fresh bulbs for forcing, planting the old ones in the garden, where they become established and flower year after year with little or no cultural attention. We are glad you have succeeded so well with the other plants on which advice was given. The small spray was accidentally mislaid. Can you send another specimen for examination?

Melons Sweating (*H. B.*).—In all probability the wet state of the Melons was the result of a too low night temperature and the consequent deposition of moisture by condensation, and possibly, also, you did not admit air soon enough in the morning. If you maintain a night temperature of 65°, with a little ventilation at the top of the pit or frame, and open the ventilators further as soon as the heat rises in the morning, increasing the air with each 5° increase of temperature, you will not be troubled with

further "sweating," which is dangerous when so pronounced as described in your letter. The specimen was not in condition to be named. If you will send another so packed that it arrives in a fresh state it shall be attended to.

Roses for Roof (Old Subscriber).—You could not do better than plant Roses, and we do not doubt you will get a better return by so doing than if you retained the Vines. Plant three of *Maréchal Niel*, the same quantity of *Gloire de Dijon*, two *Lamarque*, two *Cheshunt Hybrid*, and one each of *Belle Lyonnaise* and *Reine Marie Henriette*. These are large strong growers suitable for furnishing the roof. If you can so arrange the planting as to include some of the smaller and less vigorous Tea varieties near the front of the house we should advise you to do so, for they will yield you a succession of bloom over a lengthened period. The following would do well in your house:—*Safrano*, *Niphetos*, *Madame Lambard*, *Marie Van Houtte*, *Etoile de Lyon*, *Alba Rosea*, *Catherine Mermet*, *Souvenir d'un Ami*, and *Innocente Pirola*. If more plants are required to make up the number plant extra plants of the second, third, and last but one as named.

Camellia Leaves Scorched (Inquirer).—The blotches on the leaves have not been caused by insects, but are the result of excessive evaporation—that is to say, the moisture has passed from them more rapidly than it has been supplied by the roots, hence the shrinkage of the leaves near the edges. Either the root-action of the plant is defective or it has not had sufficient water. Make the soil over the roots quite black with soot and water it in, giving sufficient water to pass quite through the border. Syringe the plant at the least twice a day in dry weather and keep it quite shaded, as plants thus enfeebled cannot endure the direct rays of the sun. Your object must be to lessen evaporation from the foliage, and if you effect this the plant, if not "too far gone," may possibly be restored.

Names of Fruit (C. Spider).—Winter Greening, or, as you say, French Crab.

Names of Plants (W. J.).—*Limnanthes Douglasii*. (R. F.).—*Hibiscus mutabilis*. (J. R. H.).—1, *Iris graminea*; 2, *Gladiolus byzantinus*; 3, *Centranthus ruber*; 4, *Adiantum Capillus-Veneris*. (South Wilts).—1, *Fuchsia splendens*; 2, *Oxalis corniculata rubra*, and is not the Shamrock, which is *Oxalis acetosella*; 3, *Alonsoa incisa*. (B.).—*Trifolium repens*, not the Shamrock. See reply above. (P. H.).—The blue flower is *Muscari monstrosum*, and the yellow one *Asphodelus luteus*. (R. L. K.).—*Avena elatior*, Tall Oat Grass. (M. F. G.).—*Cynoglossum officinale*. (W. W.).—1, *Staphylea pinnata*; 2, *Orchis maculata*; 3, *Habenaria bifolia*; 4, not recognisable; 5, *Cephalanthera ensifolia*; 6, *Allium ursinum*.

COVENT GARDEN MARKET.—JUNE 25TH.

HEAVY supplies of outdoor Strawberries to hand this week, and business somewhat quieter. Prices unaltered, with the exception of Strawberries, which are fast reaching their lowest value.

THE LONGHORN BREED OF CATTLE.

THE history and peculiarities of this breed of cattle are interesting and becoming more important for various reasons—its antiquity and the revival which has latterly taken place. Although the breeders of cattle generally in this country have their favourites at the present time, yet about the year 1720, and even up to a hundred years ago, Longhorns occupied a position in public favour very like that held now by the Shorthorn. We have no record of their having been sold at any period for thousands of pounds per head, but it must be remembered that money was not so plentiful as it is now. Still the breed of Long-

horns in the olden time obtained hundreds for their choicest animals of the best herds, for they were considered a hundred years ago as the most profitable cattle, both as producers of beef and of cheese, with which the farmers could stock their pastures, especially in the midland and north-midland counties. They did not, however, for long remain in the general estimation of the cattle breeders, for after the two first decades of the present century they were nearly superseded by the then rising Shorthorns, which filled their places.

The Longhorn cattle, their history and progress, has been well treated in an essay written by Mr. J. Nevill Fitt in the *Journal of the Royal Agricultural Society of England* in 1876, from which we propose to make occasional quotations; for although Mr. Fitt may not himself have been an enthusiast in their favour, yet he seems by dint of great research and well-described historical facts connected with this breed to have got together not only a body of practical facts upon the subject, but combined them in a most interesting manner in the valuable essay above referred to. Mr. Fitt observes:—"Well might it have been predicted when Bates, the Collings, and other noted breeders arose with giant-like energy to take the new comers in hand, and expended time, skill, and capital on their behalf, that the curly coats (Longhorns) would have a tough fight to maintain their supremacy. But the citadel was doomed to fall from weakness within rather than from assaults from without, and it was the want of due knowledge in the science of breeding amongst those who held them rather than any preponderating superiority on the part of their rivals that caused the gradual displacement of the Longhorn from our pastures and steadings. In fact, the Longhorn breeders attempted too much, and the breed may veritably be said to have been killed with kindness. They sought for over-refinement, and forgot that it is much more easy to lose than to regain hardy qualities and big bone, which any breed must have to be profitable in the hands of tenant farmers generally. Qualities for which the Longhorns had for many years been especially famous were ignored, and others of an exotic character endeavoured to be implanted on him, such as must eventually prove the ruin of any breed in which they are perpetuated without some counteracting influence.

"Those men who first took in hand the breed in its rough state and made it famous gradually passed away. Yet there were a few men who, knowing the intrinsic merits of the breed, stuck to them through good report and evil report, and, gaining experience by the failures of their predecessors, avoided the shoals and quicksands on which others had been wrecked. Patiently abiding their time they have held on long enough to see their favourites once more come into well-deserved esteem and take their place with our Shorthorns, Herefords, Devons, and so forth. With regard to his derivation little is known. Wherever he may have originally come from, I can only trace the history of the Longhorn with any accuracy from the northern parts of Leicestershire and the adjacent county of Derbyshire. He seems to have been first brought to perfection on the borders of the wild district known as Charnwood Forest, which at the time these cattle first came into notoriety was probably as wild and uncultivated as any spot to be found in England. Right well do these picturesque cattle match well with its sylvan beauty, and I am also tempted at times to think that the early improvers of the breed must have taken them in hand as much with an eye to the general fitness of things as for the sake of beef and cheese."

It appears from all we can learn that the earliest attempt in connection with the improvement of the Longhorns was made by Sir Thomas Gresley of Drakelow House, Burton, who took such delight in keeping a dairy of cows similar in colour and shape as early as the year 1720, and therefore many years before Bakewell assumed a position of celebrity and note amongst Longhorn breeders. To Sir Thomas, however, the majority of those who wished to excel and to improve their herds had recourse, and the generality of Longhorn cattle of the best type and style trace back to his time. It is also stated with great confidence that a breeder by the name of Webster of Canley, near Coventry, next made his appearance upon the scene. It seems that he also used the Drakelow cattle and crossed them with bulls from Cumberland and Westmoreland, which counties, without doubt, must have possessed valuable herds at that early period; and Mr. J. N. Fitt tells us that, "strange to say, of late years I have found some of the best breeders taking exactly a similar course, and going to those districts to procure bulls. Webster's best bull was Bloxidge, who was the sire of some very remarkable stock. Bakewell laid the foundation of his herd with a couple of Canley heifers and, like Webster's, a Westmoreland bull. So here we get the line direct to Sir Thomas Gresley's herd, and from him the blood was imparted to nearly all the herds of the country."

As we have constantly seen some of the Longhorns at the cattle shows we have been struck with their hardy and robust appearance as compared with some of the best-bred Shorthorns and Herefords. The day may come when a breed like the Longhorn may stand us in good stead when, from weakness of constitution consequent upon high breeding and high feeding, cattle of the present and days to come may be greatly benefited by the Longhorn blood in order to strengthen the constitution of some of our most cherished herds. We have seen in the above remarks as made by Mr. Nevill Fitt that the Longhorns at the early period lost caste, and, as it were, nearly killed with kindness, and that their constitutions under the treatment now resorted to for the prize-winning stock and herds of the present day became weakened. This will arise again in the Shorthorns, &c., at a future time without doubt more or less, and therefore it is highly desirable that the Longhorns as we now see them should be maintained as nearly as possible as they have been of late years, for it may prove eventually a mine of wealth to the best cattle breeders of the future. By utilising the Longhorn blood many herds may be improved, but especially of the Herefords for the Longhorn and Hereford in a cross would nick better than any other of our leading herds. We must also remember that the Welsh and some other breeds amongst which many inferior herds may be seen, would be greatly improved by a single cross with the Longhorn without loss of character, but especially those breeds which are found deficient in lean meat as well as weight for age and early maturity. We entertain a strong opinion that half-bred Hereford and Longhorn would be a cross capable of furnishing rare and valuable specimens of baby beef, and would make out great weights at two years old when boxed during their whole life, as we have frequently done it with Shorthorns. With the strong constitution of the Longhorn, combined with the aptitude to fatten of the Hereford, we can clearly see that the result would be very beneficial to the breeder and feeder of such a cross, for it is well known that the generality of baby beef animals, although often very fat, are more like veal than beef, yet with a full amount of firm lean flesh combined and obtained, as it would be by the Longhorn cross, would be a move in the right direction.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are still engaged by turns with hay-carting and preparing for seeding the land appointed for common Turnips. Swede-seeding having been finished, also the Cabbage-planting, the growth of which has been greatly improved by the late rains—in fact, we have never been favoured with finer rains than those which occurred about the 10th of June, which have been plentiful without being flooding as thunderstorms are frequently. The first growth of Mustard has been ploughed in, and the land worked fine as fast as ploughed and the second growth seeded for, which, after these fine rains, will be sure to be of quick growth, giving plenty of time before harvest for ploughing in and re-seeding for the third growth. That also must be ploughed in and the land seeded to Wheat without further manure, because this practice has been proved equal to a full crop of Wheat with Lent corn and Clover to follow without any further manuring; and if the second growth of Clover is ploughed in also the next crop of Wheat will be also abundant without any further manuring. Horse-hoeing the Mangolds, the Cabbages, the Carrots, and the Swedes will be the next work before hand-hoeing. As soon as the field hay has been stacked the meadow grass will be cut and made as soon as possible, for we have a large heap of earth and other composts now ready for laying-out as fast as the meadows are cleared of the hay. This will bring a full aftermath for feeding with young cattle, and prove equal to a full crop of hay the next year. We are now cutting and have nearly finished the early Trifolium now cutting for soiling horses and cattle; the late variety of white-blossomed will follow up and hold out until the second week of July, when the land will be all rafter-ploughed, worked down and scarified, then drilled with Greystone Turnip seed, manured with $2\frac{1}{2}$ cwt. per acre of bone superphosphate. In this way last year we got Turnip plants of thick and full foliage, the whole being ploughed in without any other manure for Wheat, and the Wheat promises an abundant crop of straw. The yield, of course, will depend on a favourable time for setting the grain and ripening.

Hand Labour.—Men and horses are mowing the grass for hay, and two horses being constantly engaged attached to the mower, but by relays of fresh horses every four or five hours, because it is very hard work although the crop is not so heavy this year as it has been on the average of a few past seasons. Men will be engaged at the stacking of hay, hoeing of Mangolds, Carrots, Cabbage, and Swedes as fast as they become ready for singling. In fact, after the second horse-hoeing and the Mangold plants properly set out and singled, $1\frac{1}{2}$ lb. of Greystone Turnip seed per acre will be sown broadcast over the field both of Mangolds and Swedes as they are drilled, or should be at 30 inches to 36 inches apart between the lines, in order to give the young Turnip plants a little light and air to favour the growth of foliage, for the object is to only produce gross foliage, to be ploughed in with greens of the Mangolds and Swedes, as the crops will be pulled and carted to the store for horses, cattle, and

dairy cows in the winter, for we entirely repudiate the feeding of sheep on the land in the winter months. The feeding of them on the land is a great drawback and displacement of the seeding for corn and sale crops, whereas cattle are fed at the homestead without injury to the land, especially dairy cows when properly managed and provided for by stores of Mangold, Cabbage, Carrots, and white Oat straw.

Live Stock.—Where a breeding flock is kept of the horned Dorset and Somerset ewes the rams now should be in service in order that the lambing time may commence in November; but the off-going ewes will have been with the rams for some time past in order that they may bring their lambs in October. The early Dorset Downs should now also be with the rams, for many of these flocks where kept on pastures of limestone subsoil will often bring lambs in November, and when thus early to lamb will make a long price to go into the southern and home counties for producing early lambs for the Metropolitan market at or before Easter. Bullocks grazing for beef on the best pastures will now be doing well, but should have access to water at all times; if, however, the pastures are not first-rate, the animals should soon get some cotton cake or Maize meal, or both, and if given with cut Mangolds mixed in their skeps they will do well; in fact, on those pastures which will not feed a bullock fat without trough food, a store of Mangolds should always be retained on purpose, for it is one of the best mediums of supplementary summer feeding which can be devised. Dairy cows now require particular attention, and if possible should be brought to the stalls in sunny weather during the heat of the day, getting a good bait of green fodder at milking time, both night and morning, of Clover, Trifolium, Vetches, &c.; and when in their stalls they will lie down in quietude as compared with the frantic excitement they suffer oftentimes under the attack of flies when in the fields, park lands, and pastures, for even when they take shelter under the trees they are still teased by the flies. This is frequently the cause not only of a diminution of the flow of milk in the summer, but also induces the animals to go dry at an earlier period. The castration of all male colts over a year old should not be longer deferred; and after the operation has been carefully performed by a skilful veterinary the animal should be kept in a quiet shady building or barn now until quite recovered before being allowed to run the pastures by day and by night. In the case of setting out an establishment for the suckling of calves for veal, it is best to arrange for taking such a number of calves as required per week or month with dealers who are prepared to supply them rather than trust to buying in the ordinary markets.

OUR LETTER BOX.

Houses for Cows and Calves (T. S.).—Our plan is to have the cows in boxes standing tethered two in each and their calves tethered behind them. These boxes are about 9 feet wide by 12 feet long, filled with earth at the bottom about 18 inches deep and littered with short straw as cleanliness dictates. This at all times furnishes a pure atmosphere for the calves to live in, particularly in the summer months when the cows go out to graze and only come in to suckle the calves twice in the twenty-four hours. The boxes should be made warm and the light excluded as much as possible, so that the calves should be induced to lie and sleep the greater part of the time between the hours of feeding and suckling, and also to prevent them being disturbed and annoyed by flies, which always follow the sunlight. In ordinary cowsheds the calves seldom have good healthy lairs, the air being often more or less impregnated with ammonia. This is often the cause of diarrhoea, the most fatal and damaging complaint to which calves are subject. It should be borne in mind that it is of far more consequence to maintain the health of veal calves than of the weaned calves, because the latter may live through it without any serious injury; but not so with the former, for although they may recover their health they will never recover the time lost whilst suffering from disease of any kind.

REMARKS.

- 15th.—Generally fine.
 16th.—Rather cloudy.
 17th.—Generally dull, and a sprinkle of rain about 6.30 P.M., but not measurable.
 18th.—Another dull day, very little sun.
 19th.—Dull morning and frequently overcast.
 20th.—Slight fog early, and generally cloudy.
 21st.—Clear morning, but cloudy afterwards

A dry week of nearly average temperature, but with an excess of cloud.—G. J. SYMONS
